Valley Water

FEBRUARY 25, 2025

Anderson Dam Seismic Retrofit Project

Final Environmental Impact Report

SCH # 2013082052 **VOL #1** **Final EIR - Part 1**

Table of Contents

Chapter ES Executive Summary ES-1
ES.1 Purpose and Contents of the EIR ES-1
ES.2 Background ES-2
ES.3 Project Purpose ES-3
ES.3.1 FERC Requirements ES-4
ES.3.2 DSOD Requirements ES-4
ES.4 Project Location ES-4
ES.4.1 Regional Area – Coyote Creek Watershed ES-4
ES.4.2 Project Area – Anderson Dam and Reservoir, Coyote Creek, Ogier Ponds, and Coyote Percolation Pond ES-8
ES.5 Project Objectives and Benefits ES-11
ES.5.1 Project Objectives ES-11
ES.5.2 Project Benefits ES-11
ES.6 Description of the Proposed Project ES-11
ES.6.1 Seismic Retrofit ES-12
ES.6.2 Conservation Measures ES-18
ES.6.3 Construction Monitoring ES-21
ES.6.4 Post-Construction Anderson Dam Facilities Operations and Maintenance ES-23
ES.6.5 Anderson Dam Facilities Maintenance ES-24
ES.6.6 Post-Construction Conservation Measures Operations and Maintenance ES-25
ES.6.7 Post-Construction Project and FAHCE Adaptive Management Program ES-26
ES.6.8 Avoidance and Minimization Measures ES-26
ES.7 Permits, Approvals, and Consultations ES-27
ES.7.1 Water Rights Amendments ES-27
ES.8 Summary of Project Impacts and Mitigation Measures ES-27
ES.8.1 Alternatives Evaluated in the Draft EIR ES-41
ES.8.2 No Project Alternative ES-41
ES.8.3 Increased Dredge Alternative ES-42
ES.8.4 Anderson Dam Operated with FAHCE-Plus Modified Rule Curves (FAHCE-Plus Modified) Alternative ES-42
ES.8.5 Modification of Ogier Ponds Lands West of Pond 1 and Pond 2 to Protect Ponds and to Avoid Trucking (Ogier Ponds Alternative) ES-44

ES.8.6 Comparison of Proposed Project and Alternative Impacts ES-44
ES.8.7 Environmentally Superior Alternative ES-54
ES.9 Areas of Known Controversy ES-54
ES.10 Issues to be Resolved ES-55
ES.11 Stakeholder Coordination and Public Involvement Process ES-55
ES.11.1 Stakeholder Coordination and Engagement Process ES-55
ES.11.2 EIR Scoping ES-55
ES.11.3 Draft EIR Public Comment Period... ES-55
ES.11.4 Partially Recirculated Draft EIR Public Comment Period................ ES-56
ES.11.5 Preparation of Final Environmental Impact Report and Project Approval Process ES-57
ES.12 References ES-60

Chapter 1 Introduction 1-1
1.1 Geographic Area Overview 1-2
1.1.1 Coyote Creek Watershed... 1-2
1.1.2 Anderson Reservoir and Dam 1-2
1.2 Valley Water Mission 1-3
1.3 Project Background 1-5
1.3.1 Project Need and Purpose 1-5
1.3.2 Project History 1-6
1.3.3 FERC Order Compliance Project 1-7
1.3.4 Fish and Aquatic Habitat Collaborative Effort 1-9
1.3.5 Coyote Creek Water Rights 1-12
1.4 Overview of California Environmental Quality Act Requirements 1-13
1.5 Scope and Intent of this Environmental Impact Report 1-13
1.6 Selected Other Related Valley Water Projects and Programs (Not within Scope of this Document) 1-14
1.7 Agency Coordination, and Public Involvement, and CEQA Process 1-16
1.7.1 Agency Coordination 1-16
1.7.2 Public and Interest Group Engagement Process 1-17
1.7.3 California Environmental Quality Act Scoping Process 1-17
1.7.4 Tribal Consultation 1-18
1.7.5 Draft Environmental Impact Report Comments Period 1-18
1.7.6 Partially Recirculated Draft EIR Public Comment Period................. 1-19
1.7.7 Preparation of Final Environmental Impact Report and Project Approval Process 1-20
1.8 Organization of this Draft Final Environmental Impact Report..................... 1-22

1.9 References ... 1-25

Chapter 2 Project Description ... 2-1

2.1 Introduction ... 2-1
2.2 Project Location ... 2-1
2.2.1 Regional Area – Coyote Creek Watershed ... 2-1
2.2.2 Project Area – Anderson Dam and Reservoir, Coyote Creek, Ogier Ponds, and Coyote Percolation Pond ... 2-6
2.2.3 Surrounding Land Uses ... 2-12
2.3 Project Purpose, Objectives, and Benefits ... 2-12
2.3.1 Project Purpose ... 2-12
2.3.2 Project Objectives ... 2-13
2.3.3 Project Benefits ... 2-13
2.4 Overview of Project Components ... 2-13
2.5 Seismic Retrofit Construction ... 2-37
2.5.1 Construction Process and Phasing ... 2-37
2.5.2 Seismic Retrofit Site Mobilization and Preparation ... 2-45
2.5.3 Reservoir Operations During Seismic Retrofit Construction ... 2-57
2.5.4 Construction Details and Methods for Selected Project Components ... 2-60
2.5.5 Seismic Retrofit Construction Utilities and Services ... 2-74
2.5.6 Site Restoration ... 2-76
2.6 Conservation Measures Construction ... 2-77
2.6.1 Ogier Ponds CM ... 2-77
2.6.2 Maintenance of the North Channel Reach Extension ... 2-87
2.6.3 Sediment Augmentation Program ... 2-90
2.6.4 Phase 2 Coyote Percolation Dam Fish Passage Enhancements ... 2-94
2.6.5 Maintenance Activities at the Live Oak Restoration Reach ... 2-99
2.7 Construction Phase Monitoring ... 2-100
2.7.1 Water Quality Monitoring: Water Temperature, Dissolved Oxygen, Turbidity, and pH ... 2-100
2.7.2 Sediment Deposition Monitoring ... 2-102
2.7.3 Groundwater Monitoring ... 2-104
2.7.4 Vegetation Monitoring ... 2-104
2.7.5 Fisheries Monitoring ... 2-105
2.7.6 Reptile Monitoring ... 2-109
2.7.7 Terrestrial Animal Monitoring ... 2-110

2.8 Post-Construction Anderson Dam Facilities Operations and Maintenance 2-110
2.8.1 Reservoir Refilling and Inflow 2-111
2.8.2 Reservoir Outflow 2-111
2.8.3 Post-Construction Operational Rule Curves 2-114
2.8.4 Imported Water Storage and Releases 2-120
2.8.5 Anderson Dam and Pipeline Facilities Maintenance 2-120
2.9 Post-Construction Conservation Measures Operations and Maintenance 2-125
2.9.1 CDL and Cross Valley Pipeline Extension Pipeline Maintenance for Imported Water and Dam Releases 2-125
2.9.2 Ogier Ponds Operations and Maintenance 2-125
2.9.3 North Channel Reach Extension 2-126
2.9.4 Sediment Augmentation Program Maintenance Operations 2-127
2.9.5 Phase 2 Coyote Percolation Dam Operations and Maintenance 2-128
2.9.6 Maintenance Activities at the Live Oak Restoration Reach 2-129
2.10 Project and FAHCE Adaptive Management Program 2-130
2.11 Avoidance and Minimization Measures 2-133
2.11.1 Best Management Practices 2-133
2.11.2 Valley Habitat Plan Conditions 2-146
2.12 Permits, Approvals, and Consultations 2-146
2.12.1 Water Rights Amendments 2-148
2.13 References 2-150

Chapter 3 Environmental and Regulatory Setting and Impact Analysis 3-1
3.0 Introduction 3-1
3.0.1 Regional Environmental Setting and Project Area 3-1
3.0.2 Environmental Baselines 3-1
3.0.3 Environmental Resource Topic Sections 3-6
3.0.4 General Methodology 3-8
3.0.5 Resource Topics Dismissed from Further Review 3-12
3.0.6 Approach to Cumulative Impacts 3-13
3.0.7 References 3-27
3.1 Aesthetics 3.1-1
3.1.1 Terminology Overview 3.1-1
3.1.2 Environmental Setting 3.1-2
3.1.3 Regulatory Setting 3.1-34
3.1.4 Methodology and Approach to Impact Analysis 3.1-35

3.1.5 Impact Analysis 3.1-41
3.1.6 Cumulative Aesthetic Impacts 3.1-63
3.1.7 References 3.1-70
3.2 Agriculture and Forestry Resources 3.2-1
3.2.1 Environmental Setting 3.2-1
3.2.2 Regulatory Setting 3.2-4
3.2.3 Methodology and Approach to Impact Analysis 3.2-13
3.2.4 Impact Analysis 3.2-17
3.2.5 Cumulative Agricultural Resources 3.2-22
3.2.6 References 3.2-25
3.3 Air Quality 3.3-1
3.3.1 Environmental Setting 3.3-1
3.3.2 Regulatory Setting 3.3-11
3.3.3 Methodology and Approach to Impact Analysis 3.3-23
3.3.4 Impact Analysis 3.3-33
3.3.5 Cumulative Impacts 3.3-56
3.3.6 References 3.3-63
3.4 Biological Resources—Fisheries Resources 3.4-1
3.4.1 Environmental Setting 3.4-3
3.4.2 Regulatory Setting 3.4-42
3.4.3 Methodology and Approach to Impact Analysis 3.4-50
3.4.4 Impact Analysis 3.4-79
3.4.5 Cumulative Impacts 3.4-189
3.4.6 References 3.4-193
3.5 Biological Resources—Wildlife and Terrestrial Resources 3.5-1
3.5.1 Environmental Setting 3.5-3
3.5.2 Regulatory Setting 3.5-53
3.5.3 Methodology and Approach to Impact Analysis 3.5-61
3.5.4 Impact Analysis 3.5-93
3.5.5 Cumulative Impacts 3.5-211
3.5.6 References 3.5-224
3.6 Cultural Resources 3.6-1
3.6.1 Study Area for Cultural Resources 3.6-1
3.6.2 Environmental Setting 3.6-8
3.6.3 Regulatory Setting 3.6-29
3.6.4 Methodology and Approach to Impact Analysis 3.6-33
3.6.5 Impact Analysis 3.6-38

3.6.6 Cumulative Cultural Resources Impacts ... 3.6-49
3.6.7 References ... 3.6-54
3.7 Energy ... 3.7-1
3.7.1 Environmental Setting ... 3.7-1
3.7.2 Regulatory Setting ... 3.7-9
3.7.3 Methodology and Approach to Impact Analysis ... 3.7-19
3.7.4 Impact Analysis ... 3.7-25
3.7.5 Cumulative Impacts ... 3.7-39
3.7.6 References ... 3.7-44
3.8 Geology and Soils ... 3.8-1
3.8.1 Environmental Setting ... 3.8-1
3.8.2 Regulatory Setting ... 3.8-36
3.8.3 Methodology and Approach to Impact Analysis ... 3.8-48
3.8.4 Impact Analysis ... 3.8-55
3.8.5 Cumulative Impacts ... 3.8-79
3.8.6 References ... 3.8-88
3.9 Greenhouse Gas Emissions ... 3.9-1
3.9.1 Environmental Setting ... 3.9-1
3.9.2 Regulatory Setting ... 3.9-4
3.9.3 Methodology and Approach to Impact Analysis ... 3.9-14
3.9.4 Impact Analysis ... 3.9-19
3.9.5 Cumulative Impacts ... 3.9-30
3.9.6 References ... 3.9-36
3.10 Hazards and Hazardous Materials ... 3.10-1
3.10.1 Environmental Setting ... 3.10-5
3.10.2 Regulatory Setting ... 3.10-15
3.10.3 Methodology and Approach to Impact Analysis ... 3.10-20
3.10.4 Impact Analysis ... 3.10-25
3.10.5 Cumulative Impacts ... 3.10-40
3.10.6 References ... 3.10-51
3.11 Hydrology ... 3.11-1
3.11.1 Environmental Setting ... 3.11-1
3.11.2 Regulatory Setting ... 3.11-13
3.11.3 Methodology and Approach to Impact Analysis ... 3.11-26
3.11.4 Impact Analysis ... 3.11-34
3.11.5 Cumulative Impacts ... 3.11-78
3.11.6 References ... 3.11-102

3.12 Groundwater Resources 3.12-1
3.12.1 Environmental Setting 3.12-1
3.12.2 Regulatory Setting 3.12-11
3.12.3 Methodology and Approach to Impact Analysis 3.12-18
3.12.4 Impact Analysis 3.12-23
3.12.5 Cumulative Impacts 3.12-46
3.12.6 References 3.12-55
3.13 Water Supply 3.13-1
3.13.1 Environmental Setting 3.13-1
3.13.2 Regulatory Setting 3.13-9
3.13.3 Methodology and Approach to Impact Analysis 3.13-11
3.13.4 Impact Analysis 3.13-14
3.13.5 Cumulative Impacts 3.13-30
3.13.6 References 3.13-35
3.14 Water Quality 3.14-1
3.14.1 Environmental Setting 3.14-1
3.14.2 Regulatory Setting 3.14-10
3.14.3 Methodology and Approach to Impact Analysis 3.14-18
3.14.4 Impact Analysis 3.14-30
3.14.5 Cumulative Impacts 3.14-72
3.14.6 References 3.14-79
3.15 Land Use 3.15-1
3.15.1 Environmental Setting 3.15-1
3.15.2 Regulatory Setting 3.15-20
3.15.3 Methodology and Approach to Impact Analysis 3.15-25
3.15.4 Impact Analysis 3.15-29
3.15.5 Cumulative Impacts 3.15-38
3.15.6 References 3.15-41
3.16 Noise and Vibration 3.16-1
3.16.1 Environmental Setting 3.16-1
3.16.2 Regulatory Setting 3.16-15
3.16.3 Methodology and Approach to Impact Analysis 3.16-20
3.16.4 Impact Analysis 3.16-31
3.16.5 Cumulative Impacts 3.16-78
3.16.6 References 3.16-82
3.17 Public Services 3.17-1
3.17.1 Environmental Setting 3.17-1

3.17.2 Regulatory Setting 3.17-6
3.17.3 Methodology and Approach to Impact Analysis 3.17-12
3.17.4 Impact Analysis 3.17-16
3.17.5 Cumulative Impacts 3.17-24
3.17.6 References 3.17-29
3.18 Recreation 3.18-1
3.18.1 Environmental Setting 3.18-1
3.18.2 Regulatory Setting 3.18-30
3.18.3 Methodology and Approach to Impact Analysis 3.18-34
3.18.4 Impact Analysis 3.18-54
3.18.5 Cumulative Impacts 3.18-64
3.18.6 References 3.18-70
3.19 Transportation 3.19-1
3.19.1 Environmental Setting 3.19-4
3.19.2 Regulatory Setting 3.19-10
3.19.3 Methodology and Approach to Impact Analysis 3.19-19
3.19.4 Impact Analysis 3.19-29
3.19.5 Cumulative Impacts 3.19-43
3.19.6 References 3.19-49
3.20 Tribal Cultural Resources 3.20-1
3.20.1 Environmental Setting 3.20-2
3.20.2 Regulatory Setting 3.20-8
3.20.3 Methodology and Approach to Impact Analysis 3.20-10
3.20.4 Impact Analysis 3.20-14
3.20.5 Cumulative Impacts 3.20-21
3.20.6 References 3.20-24
3.21 Utilities and Service Systems 3.21-1
3.21.1 Environmental Setting 3.21-1
3.21.2 Regulatory Setting 3.21-4
3.21.3 Methodology and Approach to Impact Analysis 3.21-11
3.21.4 Impact Analysis 3.21-17
3.21.5 Cumulative Impact - Utilities and Service Systems 3.21-23
3.21.6 References 3.21-27
3.22 Wildfire 3.22-1
3.22.1 Environmental Setting 3.22-1
3.22.2 Regulatory Setting 3.22-13
3.22.3 Methodology and Approach to Impact Analysis 3.22-19

3.22.4 Impact Analysis ... 3.22-23
3.22.5 Cumulative Impacts ... 3.22-33
3.22.6 References ... 3.22-40

Chapter 4 Other Statutory Requirements ... 4-1
4.1 Introduction ... 4-1
4.2 Irreversible Impacts ... 4-1
4.3 Significant and Unavoidable Impacts ... 4-1
4.4 Growth Inducement ... 4-3

Chapter 5 Alternatives ... 5-1
5.1 Introduction ... 5-1
5.2 CEQA Requirements ... 5-1
5.3 Alternatives Development Process ... 5-2
5.3.1 Project Purpose and Objectives, ... 5-2
5.3.2 Significant Environmental Impacts of the Project ... 5-3
5.3.3 Alternatives Development and Screening ... 5-7
5.3.4 Preliminary Conceptual Design Process ... 5-7
5.3.5 Alternatives Submitted during EIR Scoping ... 5-8
5.4 Potential Alternatives Considered and Dismissed ... 5-9
5.4.1 Operation of Anderson Dam for Flood Risk Reduction Only ... 5-10
5.4.2 Removal of Anderson Dam and Provision of Alternative Water Supply Sources (Removal of Anderson Dam Alternative) ... 5-11
5.4.3 Project with Downstream Fix Only ... 5-12
5.4.4 Reduction of Excavation from Anderson Dam Embankment ... 5-13
5.4.5 Use of Offsite Borrow Materials and Cut Material Off-Hauled ... 5-13
5.4.6 Extended Construction Schedule Alternative ... 5-14
5.5 Alternatives Evaluated in the Draft EIR ... 5-14
5.5.1 No Project Alternative ... 5-14
5.5.2 Increased Dredge Alternative ... 5-16
5.5.3 Anderson Dam Operated with FAHCE-Plus Modified Rule Curves (FAHCE-Plus Modified) Alternative ... 5-19
5.5.4 Modification of Ogier Ponds Lands West of Pond 1 and Pond 2 to Protect Ponds and to Avoid Trucking (Ogier Ponds Alternative) ... 5-27
5.6 Methodology for Evaluating Alternatives ... 5-28
5.7 Organization for Alternatives Impact Analysis ... 5-28
5.8 Comparative Summary of Alternatives ... 5-29
5.9 Alternatives Impact Analysis ... 5-39

5.9.1 No Project Alternative ... 5-39
5.9.2 Increased Dredge Alternative ... 5-50
5.9.3 FAHCE-Plus Modified Alternative ... 5-86
5.9.4 Ogier Ponds Alternative ... 5-125
5.10 Environmentally Superior Alternative ... 5-161
5.11 References ... 5-162

Chapter 6 List of Preparers and Contributors ... 6-1

Chapter 7 Draft EIR Comments and Responses ... 7-1
7.1 Introduction ... 7-1
7.2 Master Responses to Comments ... 7-5
7.2.1 Master Response 1 – Alternative Designs for Ogier Ponds ... 7-5
7.2.2 Master Response 2 – Steelhead Impacts ... 7-12
7.2.3 Master Response 3 – VHP Reduction of Impacts to Less than Significant ... 7-20
7.2.4 Master Response 4 – Impacts of FOCP and ADSRP related to Rosendin Park Area Closures ... 7-32
7.2.5 Master Response 5 – Impacts of FOCP and ADSRP on Feral Pig Presence ... 7-41
7.2.6 Master Response 6 – Adequacy of EIR Baselines ... 7-46
7.2.7 Master Response 7 – Impacts of FOCP and ADSRP on Wildfire Risks ... 7-53
7.3 Individual Responses to Comments ... 7-63

Chapter 8 Partially Recirculated Draft EIR Comments and Responses ... 8-1
8.1 Introduction ... 8-1
8.2 Master Responses to Comments ... 8-2
8.3 Responses to Comments ... 8-8
8.4 References ... 8-96

Chapter ES
Executive Summary

The Santa Clara Valley Water District (Valley Water) is proposing the Anderson Dam Seismic Retrofit Project (Project, or ADSRP) at Anderson Reservoir along Coyote Creek in Santa Clara County, California. The Project involves retrofitting and upgrading Anderson Dam and its associated facilities to meet Federal Energy Regulatory Commission (FERC), California Department of Water Resources, Division of Safety of Dams (DSOD), and Santa Clara Valley Water District (Valley Water) public safety requirements. The Project also includes decommissioning the hydroelectric facility at the dam, implementing Conservation Measures, and continuing to operate and maintain the dam once the retrofit has been completed.

ES.1 Purpose and Contents of the EIR

Valley Water is the lead agency responsible for compliance with the California Environmental Quality Act (CEQA) for environmental review of the Project proposed by Valley Water. CEQA requires the preparation of an Environmental Impact Report (EIR) when a project could significantly affect the physical environment. In the 2013 Initial Study prepared by Valley Water, it was determined that the Project could potentially cause significant environmental impacts and, therefore, that preparation of an EIR was required for the Project to comply with CEQA.

Valley Water has prepared this Final EIR to provide the Valley Water Board of Directors, the public, and responsible and trustee agencies reviewing this Project with information about the physical effects on the local and regional environment associated with implementation of the Project. This EIR was prepared in compliance with CEQA (Public Resources Code Section 21000 et seq.) and the CEQA Guidelines (14 California Code of Regulations Sections 15000 et seq.). This EIR describes the Project proposed by Valley Water. The document then characterizes the Project's environmental setting, discloses the range of environmental impacts of the Project, and identifies mitigation measures to avoid and/or reduce significant environmental impacts, where feasible. Also, as required under CEQA, it describes and evaluates potentially feasible alternatives to the Project that could avoid or reduce significant impacts while still meeting most, if not all, of the Project's objectives. The EIR also addresses adverse cumulative impacts and determines whether the Project or alternatives could make a substantial contribution.

The revised Draft EIR—including new comment response chapters (Chapters 7 and 8) with public comments and responses, as well as technical appendices, some of which have been revised — constitutes the Final EIR for the Project, consistent with *CEQA Guidelines* requirements. The Final EIR is an informational document prepared by the lead agency that must be considered by decision makers before approving a proposed project.

The Final EIR integrates the Draft EIR released on September 1, 2023, and the Partially Recirculated Draft EIR released on August 5, 2024. The following types of further revisions have been made to the Draft EIR and Partially Recirculated Draft EIR text. These are shown in underline and ~~strikeout~~ format.

- Minor revisions to the Project description, impact analyses, and alternatives to respond to Draft EIR and Partially Recirculated Draft EIR comments, and input from regulatory agencies
- Valley Water-initiated minor changes to the Project description, impact analyses, and alternatives
- Other minor Valley Water-initiated corrections, updates, clarifications and amplifications

See Section ES.11.5 for more details on the changes incorporated into this Final EIR. The revisions to the Project and alternatives descriptions do not change the fundamental nature or main feature of the Project or alternatives, and none of the revisions to the Draft EIR or Recirculated Draft EIR made in the Final EIR constitute significant new information requiring recirculation of the EIR (CEQA Guidelines Section 15088.5).

ES.2 Background

Anderson Dam is classified under FERC guidelines as a "High Hazard Potential" dam due to the potential incremental loss of life should failure occur. This classification is based on dam safety deficiencies associated with seismic shaking, fault offset, flood capacity, and emergency drawdown capabilities that were identified between 2008 and 2016. Deficiencies include:

- The presence of liquefiable materials in the embankment and foundation of the dam that could result in major slumping and failure of the embankment following a future large earthquake
- The presence of conditionally active faults in the foundation that could rupture the existing low-level outlet
- A spillway that has inadequate capacity to safely pass large floods
- Limitations in the dam outlet's capacity to quickly draw down the reservoir during floods or other emergency events

The Project was initiated in 2009, when Valley Water voluntarily established a restriction of the reservoir's water elevation level that was reviewed and accepted by dam safety regulators. Valley Water identified Project activities in coordination with resource agencies and stakeholders beginning in 2009 at the outset of the Project and engaged the public as part of the CEQA process with the release of a Notice of Preparation (NOP) and initiation of public scoping in 2013.

From that time through early 2020, Valley Water prepared Project design plans under the regulatory guidance of DSOD and FERC and consulted informally with environmental regulators regarding required environmental review and permitting documents for the Project. By early 2020, construction of the Project was scheduled to start in the fall of 2022.

In February 2020, FERC determined that Valley Water needed to take additional, immediate measures to further reduce the risk of failure from an earthquake and a maximum probable flood event as much as possible until the Project could be implemented. By order of FERC, Valley Water developed and implemented interim risk reduction measures (IRRM). The IRRMs required, among other things, drawdown of Anderson Reservoir and expedited construction of the Anderson Dam Tunnel Project (ADTP). FERC also directed Valley Water to secure alternative emergency water supplies and to work with FERC staff and federal, State, and local resource agencies to develop Conservation Measures to avoid and minimize environmental impacts of IRRMs.

In response to the FERC IRRM Order, Valley Water developed the FERC-ordered Compliance Project (FOCP) to implement all FERC-directed IRRMs and to identify and implement avoidance and minimization measures (AMM) necessary to address anticipated adverse environmental effects of complying with the FERC IRRM Order. The FOCP is presently underway and projected to be completed in 2026 ~~summer 2025~~. It consists of the following main Project components: drawdown of Anderson Reservoir to deadpool, construction of the Anderson Dam Tunnel along with associated operations and maintenance and measures to secure alternative water supplies and minimize environmental effects.

The Fish and Aquatic Habitat Collaborative Effort (FAHCE) is an existing, long-term program that Valley Water has agreed to implement in coordination with National Marine Fisheries Service (NMFS), California Department of Fish and Wildlife (CDFW), U.S. Fish and Wildlife Service (USFWS), and several nongovernmental environmental organizations. The program was developed as the result of a complaint filed by the Guadalupe-Coyote Resource Conservation District in 1996 with the State Water Resources Control Board (SWRCB) alleging that Valley Water operations affected fish and wildlife in violation of State laws. FAHCE seeks to improve aquatic spawning and rearing habitat and fish passage for migration to and from the watersheds of the Coyote and Stevens Creeks and Guadalupe River. The FAHCE *Settlement Agreement* (FAHCE 2003) contains a fish habitat restoration program that details those provisions defined during the FAHCE process. Valley Water has prepared the FAHCE Final Program EIR that covers the implementation of FAHCE for Guadalupe River and Stevens Creek. Appendix A of the EIR includes a Fish Habitat Restoration Plan (FHRP) and its Adaptive Management Program (AMP), which address all components of the FAHCE *Settlement Agreement,* including the long-term adaptive management of Coyote Creek measures (Valley Water 2023b).

Pursuant to the FAHCE *Settlement Agreement*, Valley Water is proposing, ~~as part of the Project,~~ changes to all of its currently held water rights in the Project area. The proposed water rights changes would incorporate Valley Water's implementation of the Coyote Creek-related measures specified in the FAHCE *Settlement Agreement* and included in the FHRP.

Between February 2020 and the time ~~this~~ the Draft EIR was prepared, Valley Water has prepared updated design plans for the Project. With respect to operations, Valley Water proposes to implement the reservoir release rule curves developed pursuant to the FAHCE *Settlement Agreement*. Construction of the Project is currently proposed to start in 2027 ~~early 2026~~.

ES.3 Project Purpose

The purpose of the Project is to seismically retrofit, maintain, and operate Anderson Dam and Reservoir to meet FERC and DSOD safety requirements, thereby allowing Valley Water to maximize water supply and related incidental benefits, while avoiding and minimizing environmental impacts of the implementation of those safety directives and requirements. Without such regulatory compliance, Valley Water would be required to maintain a very low-water level in Anderson Reservoir, which would, in turn, reduce water supplies that would otherwise be available for water supply deliveries to treatment plants, managed groundwater recharge, and maintenance of a local source of emergency water supply. Valley Water would likely have to replace those lost supplies to achieve its water supply and management goals that may result in significant cost increases, to the extent that any alternative resources are available.

ES.3.1 FERC Requirements

Per FERC requirements, the Project addresses seismic deficiencies of the dam, specifically providing a stable dam embankment capable of withstanding the maximum credible earthquakes (MCE) on the Calaveras and Coyote Creek Range Front Faults. In addition to the seismic deficiencies of the dam, the spillway presently lacks the capacity to safely pass the flood flows related to passage of the probable maximum flood (PMF) event. An updated PMF evaluation completed in 2013 (HDR 2013) predicts a peak spillway discharge of 95,800 cubic feet per second (cfs) at a reservoir stage of elevation (elev.) 652.5 feet (in the North American Vertical Datum of 1988 [NAVD 88][1]) during the PMF. The PMF flow exceeds the current spillway capacity by 50 percent and would cause overtopping of the existing dam embankment by several feet. Overtopping of the dam could lead to dam failure. FERC (as well as DSOD) dam safety criteria require that spillways be sized to safely pass PMF flows without overtopping the dam. Consequently, the spillway would be modified and improved, in conjunction with raising of the dam crest, to address this deficiency.

ES.3.2 DSOD Requirements

DSOD requires the new outlet works at Anderson Reservoir to be capable of lowering the reservoir's maximum storage depth by 10 percent within 7 days and draining its full content within 90 days (DSOD 2018 ~~2017~~), even if a fault offset were to occur. DSOD also requires the entire spillway, including the currently unlined portion of the spillway, to be able to contain the PMF, which will require deepening and hardening of the unlined portion in order to mitigate the risk of spillway failure in the event of a PMF (Valley Water 2021a).

ES.4 Project Location

ES.4.1 Regional Area – Coyote Creek Watershed

The Coyote Creek Watershed encompasses an area of over 320 square miles that includes the entire City of Milpitas, portions of San José and Morgan Hill, and unincorporated lands within Santa Clara County. The headwaters of the Coyote Creek watershed are on the east side of the county in the Diablo Range, and Coyote Creek drains into the San Francisco Bay (**Figure ES-1**).

Valley Water owns two water supply reservoirs along Coyote Creek: Anderson and Coyote (**Figure ES-1**). Anderson Dam impounds surface water runoff from 195 square miles of the Coyote Creek Watershed, which includes inflow from several tributaries and releases from Coyote Reservoir, which is approximately 1.5 miles upstream of Anderson Reservoir. Downstream of Anderson Dam, Coyote Creek flows approximately 37.5 miles north-northwest through increasingly dense urban areas before ultimately reaching San Francisco Bay. The

[1] Note: unless otherwise specified, design and reservoir elevations are reported in the NAVD 88 datum.

largest tributary to Coyote Creek downstream of Anderson Dam is Upper Penitencia Creek, which originates in the Diablo Range, several miles above Cherry Flat Reservoir (**Figure ES-1**).

Valley Water manages aquifer recharge using local water supply and imported water releases to Coyote Creek below Anderson Dam via the Coyote Discharge Line (CDL) and Cross Valley Pipeline Extension.

The portion of Coyote Creek from Anderson Dam to San Francisco Bay and Upper Penitencia Creek from Cherry Flat Reservoir to the confluence of Coyote Creek is designated as critical habitat for Central California Coast steelhead (*Oncorhynchus mykiss*), which is threatened under the Endangered Species Act (ESA). Additionally, hatchery stray Central Valley fall-run Chinook salmon (*Oncorhynchus tshawytscha*; Federal Species of Concern and State Species of Special Concern) may also use reaches of Coyote Creek.

ES.4.2 Project Area – Anderson Dam and Reservoir, Coyote Creek, Ogier Ponds, and Coyote Percolation Pond

Anderson Reservoir, formed by Anderson Dam, is located along Coyote Creek in Santa Clara County, California, approximately 18 miles southeast of downtown San José and 2.5 miles northeast of downtown Morgan Hill (**Figure ES-2**).

The Project Area refers to the area and immediate vicinity within which all construction-related activities or ground disturbance would occur and the areas and facilities that would be operated through the implementation of the Project. The Project Area includes Anderson Reservoir, Anderson Dam, Ogier Ponds, the Coyote Percolation Dam, includes the Coyote Creek channel from Anderson Dam to the Coyote Percolation Dam, lands in the immediate vicinity of Anderson Reservoir and Coyote Creek that are owned by Valley Water and the County of Santa Clara, and portions of the Cochrane Road and Coyote Road rights-of-way (**Figure ES-2**, **Figure ES-3**).

The Project Area includes the cold water management zone (CWMZ), a 6-mile ~~5-mile~~ reach of Coyote Creek between the Anderson Dam outlets and Coyote Creek Golf Drive, as defined in the FAHCE *Settlement Agreement* (FAHCE 2003). Within this reach of Coyote Creek, Anderson Dam operations could potentially adversely affect ESA-listed steelhead *(O. mykiss)*. The current functional cold water management zone (FCWMZ) effectively ends at the upstream end of Ogier Ponds, located 4 miles downstream from Anderson Dam. The FCWMZ refers to the reach between Anderson Dam and Ogier Ponds and is the area that is currently suitable habitat for *O. mykiss* (**Figure ES-1**).

ES.5 Project Objectives and Benefits

ES.5.1 Project Objectives

The objectives of the Project, consistent with FERC and DSOD dam safety requirements, are to:

1. Seismically retrofit and maintain the dam so that Valley Water may continue to operate it at capacity. This objective would be achieved by:
   - Replacing the existing dam to withstand the MCEs on the Calaveras and Coyote Creek Range Front faults
   - Replacing the existing spillway to meet FERC and DSOD safety requirements related to the safe passage of the PMF
   - Replacing the outlet works to meet current DSOD outlet works requirements and accommodate fault offset
2. Improve cost-efficiency of dam operations by decommissioning the hydroelectric facility
3. Avoid and minimize environmental effects of construction and operations

ES.5.2 Project Benefits

Implementation of the Project, including the Conservation Measures, would result in a more seismically safe dam that would allow Valley Water to better carry out water supply and groundwater recharge activities. Operational flexibility would also be improved by the Project that would:

- Minimize the risk of reservoir spills and downstream flooding
- Provide in-stream environmental flows consistent with regulatory requirements
- Restore recreational opportunities at Anderson Reservoir and along the Coyote Creek corridor

ES.6 Description of the Proposed Project

The Project consists of numerous Project components that fall into six over-arching categories:

1) **Seismic Retrofit.** Project components related to the Anderson Dam facility upgrades and improvements to stabilize and mitigate potential seismic risks and comply with current public safety requirements.
2) **Conservation Measures.** Project components designed to avoid and minimize adverse environmental impacts and, in some cases, provide environmental benefits.
3) **Construction Monitoring.** Project components include habitat and species monitoring during construction to document Project effects on the environment.
4) **Post-Construction Anderson Dam Facilities Operations and Maintenance:** Project components that involve how proposed, permanent Anderson Dam facilities would be operated and maintained following construction. These Project components include implementation of the FAHCE Phase 1 flow measures at the Anderson Dam facility, post-construction monitoring, and post-construction maintenance.

5) **Post-Construction Conservation Measure Operations and Maintenance:** Project components that involve how proposed, permanent Conservation Measure facilities would be operated and maintained following construction. These Conservation Measure facilities include implementation of the Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, Phase 2 Coyote Percolation Dam Fish Passage Enhancements (Phase 2 Coyote Percolation Dam CM), Maintenance Activities at the Live Oak Restoration Reach, and the Sediment Augmentation Program.

~~6) **Post-Construction Conservation Measure Operations and Maintenance:** Project components that involve how proposed, permanent Conservation Measure facilities would be operated and maintained following construction. These Conservation Measure facilities include implementation of the Ogier Ponds CM, North Channel Extension, Phase 2 Coyote Percolation Dam Fish Passage Enhancements (Phase 2 Coyote Percolation Dam CM), and the Sediment Augmentation Program~~

6) **Post-Construction Project and FAHCE Adaptive Management Program**: Adaptive management of all post-construction operations, and all habitat restoration Conservation Measures components would occur in accordance with the FAHCE AMP. Pursuant to the FAHCE Framework, a Project-specific ADSRP AMP has been developed. The AMP includes four key elements: measurable objectives for steelhead and salmon fisheries and their habitats; compliance monitoring, validation monitoring, effectiveness monitoring, and long-term trend monitoring; adaptive actions that may be identified to assure measurable objectives are met; and reporting.

ES.6.1 Seismic Retrofit

Construction activities for the Seismic Retrofit Project components include the following: site mobilization and preparation, including clearing and preparing staging and stockpile areas, reservoir dewatering and cofferdam construction, construction of the temporary water diversion system, dam excavation and fill (including dredging, excavation of embankment materials from borrow areas and disposal of excess materials at disposal areas), construction of the new outlet works and spillway, construction of other ancillary facilities, decommissioning of the hydroelectric facility, and site restoration. Seismic Retrofit construction is planned to occur over 7 years (**Figure ES-4**).

Dam Embankment. The existing dam would be removed and replaced with a more seismically stable dam in the same location that is designed to withstand MCEs on the Calaveras Fault and Coyote Creek Range Front Fault. The dam replacement process would begin after the reservoir is fully dewatered and Coyote Road has been removed from the top of the dam. The completed replacement dam would have a crest length of approximately 1,700 feet and a crest height of elev. 656 feet.

During the period of dam removal and replacement when the existing spillway would not be operational (see below), reservoir inflows would be conveyed past the dam site through the Stage 2 Diversion System. Inflows that exceed the diversion system’s capacity would form temporary reservoirs behind interim dams that would be in place at the end of each construction stage. To prevent the potential failure of the interim dams should overtopping occur during the wet season, and to minimize the potential for subsequent downstream flooding, an articulated concrete block-lined spillway would be constructed on the downstream slope of the interim dams to convey some volume of overtopping flow safely past the interim dams as a winterization measure (Valley Water 2022).

Dam Crest. The existing dam crest's height would be raised to elev. 656 feet to accommodate the PMF.

Spillway. The existing spillway would be removed and replaced with a fully lined spillway to accommodate safe passage of the PMF. The replacement spillway would be located within the same general footprint occupied by the existing spillway and unlined spillway channel. The new spillway crest would have the same length, elevation, and general shape as the existing spillway.

Temporary Diversion Systems. The Project includes two stages of water diversion throughout construction activities. The Stage 1 Temporary Diversion System (also known as the ADTP, which was previously constructed as part of the FOCP) would be converted to the Stage 2 Diversion System to continue to bypass flows in Coyote Creek behind Anderson Reservoir around the Project Area and return flows to lower Coyote Creek throughout Project construction.

To convert the Stage 1 Diversion System to the Stage 2 Diversion System, the Stage 1 Diversion System would be operated until the reservoir is completely dewatered, at which time construction of the Stage 2 Diversion System would begin. This conversion is expected to be completed ~~occur~~ in Year 2 of Project construction, after the reservoir is completely dewatered.

Outlet Works. A low-level outlet works (LLOW) and high-level outlet works (HLOW) would be constructed along the northern dam abutment on the south side of the spillway. The LLOW would provide discharge capacity for normal operations and most of the discharge capacity for emergency releases. The LLOW would be capable of simultaneously making releases to Coyote Creek and delivering flows to the Valley Water raw water transmission system through the Anderson Force Main. The HLOW would provide additional discharge capacity, in combination with the LLOW, in the event of an emergency.

Pipeline Realignments. Realigned sections of the Anderson Force Main and the Main Avenue Pipeline would be installed underground near the downstream base of the dam.

Installation of Dam Controls and Instrumentation. The dam would have instrumentation and controls for operation of the reservoir as well as instrumentation for monitoring dam safety specifications and reservoir levels.

Communication Lines Beyond Dam Excavation Footprint. To improve and provide communication network connectivity in the Project Area, existing telemetry cables would be replaced, and new fiber optic lines would be installed.

Temporary and Permanent Roadway Modifications. Existing roadways throughout the Project Area would be permanently modified to accommodate the Anderson Dam improvements and new Anderson Dam facilities, including roadways around the dam and on the dam crest itself.

Temporary roadway modifications include adjustment of existing ADTP access roads and construction of new access roads.

Decommissioning of Hydroelectric Facility. The hydroelectric facility located along Cochrane Road to the west of Anderson Dam would be decommissioned. Decommissioning would occur in the first year of the Seismic Retrofit construction. This process would involve coordination with

Pacific Gas and Electric Company (PG&E) for the termination of connection between the existing facility and existing PG&E infrastructure related to power generation.

Site Restoration. As construction is completed in Years 6 and 7, temporary facilities would be removed, and all temporarily disturbed areas would be restored to their preconstruction conditions, where practicable. Initial restoration would focus on those areas that would be inundated by the reservoir during reservoir refilling or that could be impacted during spilling of the reservoir. Restoration would generally include revegetating areas with native species where vegetation had been removed and repaving damaged roadways.

ES.6.1.1 Seismic Retrofit Site Mobilization and Preparation

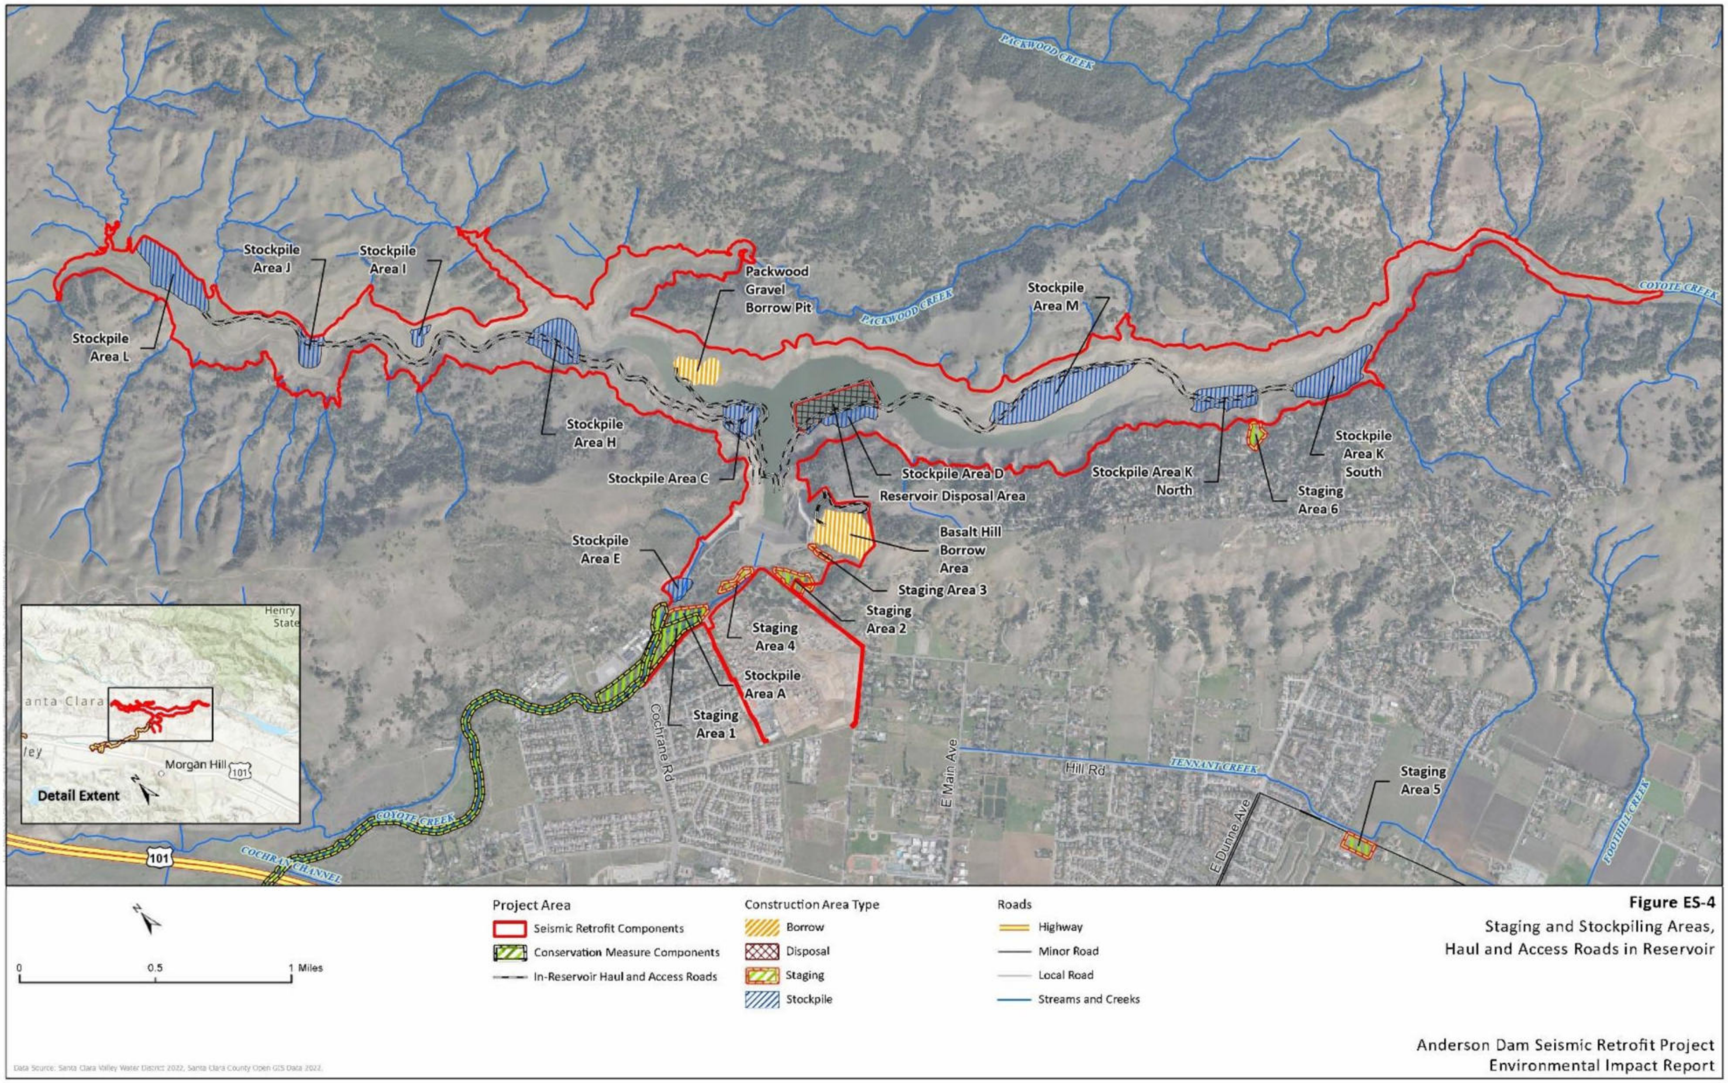
The first year of Seismic Retrofit construction would primarily include mobilization and site preparation of staging areas, stockpile areas, and access roads. Several staging areas, stockpile areas, and access roads occur within Anderson Lake County Park. These areas, along with all other recreational park areas located within the Project Area, would be closed to the public for the duration of construction.

Materials required for the replacement of the dam embankment would originate from excavations from the original dam, commercial sources from within the San Francisco Bay Area, and from two borrow sites within or adjacent to the reservoir.

Materials excavated from the dam foundation, portals, tunnels, and structures, and overburden materials from borrow areas that cannot be reused, would be disposed of within a designated Reservoir Disposal Area (**Figure ES-4**).

1 **Figure ES-4. Staging and Stockpiling Areas, Haul and Access Roads in Reservoir**

2



ES.6.1.2 Reservoir Operations During Seismic Retrofit Construction

Anderson Reservoir Operations

Anderson Reservoir would be operated to maintain the water surface at the FERC-restricted level until full reservoir dewatering occurs during Year 2. As a part of the FOCP after the completion of ADTP, the reservoir would be maintained at deadpool or, if approved by FERC, at a higher elevation that avoids or minimizes the risk of seismic failure of the dam and maintains the reservoir in a safe condition while providing more water for supply and recharge. If a higher elevation is approved by FERC, the reservoir would be brought down to deadpool (elev. 490 feet) by the end of the year before Year 1 to allow the reservoir slopes to drain prior to the in-reservoir work activities.

The Stage 1 Diversion System would operate only until the reservoir was fully dewatered during the spring of Year 2. The Stage 2 Diversion System would provide the additional flow capacity from the reservoir through the diversion system that will be required during dam removal and construction.

The Stage 2 Diversion System is intended to operate only during embankment excavation and replacement (Year 2 through Year 6). The Stage 2 Diversion System would be decommissioned during the last year of dam construction so that the LLOW can be completed. After the Stage 2 Diversion System is decommissioned, low flows would be pumped to the HLOW, for the remainder of the construction season. The LLOW would be used to control flows for the remainder of Project construction.

Water resources would be managed during construction to provide groundwater recharge and incidental environmental in-stream flows throughout construction. This would allow Valley Water to continue to meet water supply demands while continuing to provide fisheries habitat within the FCWMZ of Coyote Creek, while Anderson Reservoir is dewatered.

Coyote Creek North and South Channel Operations

Two human-made channels are located immediately downstream of the Anderson Dam outlets: the South Channel, which currently receives flows from the existing outlet works; and the re-engineered and re-established North Channel, located north of the South Channel. The two channels converge approximately 2,200 feet downstream of where the current outlet works discharges into the South Channel. Following construction of the Project, distribution of flow between the South and North Channels would be achieved by the construction of a weir at the head of each channel (Valley Water 2023a). Flows would be strategically split between the North Channel and South Channels. The weirs and flow splits have been designed to minimize the potential for erosion and maintain spawning habitat within the restored South Channel while also providing capacity for larger releases of water from Anderson Reservoir via the North Channel.

ES.6.1.3 Construction Details and Methods for Selected Project Components

Anderson Reservoir Dewatering

While water levels within Anderson Reservoir have already been substantially reduced as part of the FOCP, the reservoir would require full dewatering for construction of the Project. Dewatering of the reservoir would occur through the Stage 1 and Stage 2 Diversion Systems.

Following reservoir dewatering, inflows to the reservoir would continue to be released through the Stage 1 Diversion System until the cofferdam and temporary bypass pumping system are in place. Once the cofferdam and temporary bypass pumping system are in place, inflows would be pumped to the lowest intake of the existing outlet works while conversion of the Stage 1 Diversion System to the Stage 2 Diversion System is being completed. Once completed, low flows would pass directly into the extension pipe and the Stage 2 Diversion System. During high flows, the cofferdam would be overtopped and flows would be released directly into the diversion intake structure. At this time, the existing outlet works would be demolished.

Vegetation Clearing and Disposal

The entire Project Area, including the proposed construction staging areas, borrow areas, stockpile areas, disposal areas, parking areas, and “off-street” access roads would be cleared and grubbed. Beneficial reuse of trees, shrubs, and chip materials may occur throughout the site for restoration and soil stabilization. Vegetation that is not suitable for reuse would be disposed of on- or offsite. Topsoil from the staging areas, overburden from borrow areas, and sediments from stockpile areas would be stripped. For staging and borrow areas, stripped material would be reused where appropriate or disposed of in the Reservoir Disposal Area. For stockpile areas, stripped material would be placed nearby.

Temporary and Permanent Modifications to Recreational Facilities

As part of the Project, several of the recreation areas and facilities within Anderson Lake County Park would be temporarily or permanently closed. Some of these closures would be an extension of areas already closed for the current DSOD restrictions and for implementation of the FOCP. The remaining proposed temporary and permanent closures would occur specifically for Project construction. The Anderson Lake County Park Visitor Center would remain open throughout Project construction. This entrance would continue to provide access to the Coyote Creek Parkway, which will remain open to the public throughout construction of the Project.

ES.6.1.4 Seismic Retrofit Construction Utilities and Services

Construction Water Supply and Stormwater Drainage

Water from Coyote Creek upstream of the dam would be used for construction activities, including dust control and wetting of stockpiled materials, either by pumping from the Anderson Reservoir deadpool or by pumping from upstream of the cofferdam. Additional water would be obtained from the CDL and Main Avenue Pipeline.

Stormwater accumulating in areas upstream of the dam, in the downstream excavation area of the dam, at spillway and outlet works construction, and at the Basalt Hill Borrow Area would be released, or treated and released, into Coyote Creek or used for dust control. In staging areas and stockpile areas without access to existing infrastructure, stormwater would be managed using Valley Water's best management practices (BMP), *Best Management Practices and Santa Clara Valley Habitat Plan Conditions Incorporated in the Proposed Project*, and the SWPPP prepared to comply with the Construction General Permit.

Construction Power Supply

During construction, electrical power would be supplied to all Project facilities by PG&E. By the end of or following Project construction, PG&E would construct new underground power cables to a new distribution transformer at a permanent location near the LLOW outlet structure. PG&E would also install a new pole, service lines, and transformers at the left end of the dam.

ES.6.2 Conservation Measures

Conservation Measures have been incorporated into the Project and would be implemented throughout Project construction and/or operation phases. These measures would reduce construction-related impacts and allow for managed aquifer recharge to support water supply requirements while maintaining wetted habitat for fish, wildlife, and other groundwater-dependent habitats. Many of these Project components align with the FAHCE Phase 1 non-flow measures, as described in the FHRP, and would provide improved fish passage, steelhead spawning and rearing habitat, and restored hydrologic functions.

ES.6.2.1 Normal Operation of Coyote Reservoir

Valley Water would maintain existing normal operations of Coyote Reservoir throughout the drawdown of Anderson Reservoir and construction of the Seismic Retrofit components. This would allow Valley Water to partially retain the ability to store winter runoff in Coyote Reservoir and release it through Coyote Reservoir's outlet pipe to Coyote Creek to pass through Anderson Dam during the dry season, benefitting the native aquatic plants and animals that reside in this reach. Flows between Coyote and Anderson reservoirs within Coyote Creek would continue within current, normal ranges during the entirety of the Project.

No operational changes are proposed for Coyote Reservoir during post-construction operations. ~~Flows between Coyote and Anderson Reservoirs within Coyote Creek would continue within current, normal ranges during the entirety of the Project.~~

ES.6.2.2 Construction Period Imported Water Releases for FCWMZ (releases from Coyote Discharge Line and Cross-Valley Pipeline Extension, and Use of Chillers)

Valley Water would augment releases of local water during Project construction using other sources of supply, including imported water from the CDL and the Cross Valley Pipeline Extension. Imported water would be released into Coyote Creek within the FCWMZ and downstream of Ogier Ponds. The release of imported water would have multiple benefits, including groundwater recharge and groundwater-dependent ecosystem management, improved water quality, decreased energy costs, water supply management, support of native aquatic fish and wildlife habitat, and improved health of riparian plant communities.

During construction, if imported water releases are determined to be too warm for *O. mykiss*, chillers installed under the FOCP would be used to cool imported water prior to release via the CDL into Coyote Creek within the FCWMZ, and additional imported water would be released via the Cross Valley Pipeline Extension downstream of Ogier Ponds to continue to provide groundwater recharge below the FCWMZ.

ES.6.2.3 Ogier Ponds

Ogier Ponds currently comprises six large, artificial ponds in south San Jose that are hydrologically connected to Coyote Creek. The Ogier Ponds CM would physically separate and hydrologically disconnect Coyote Creek from Ogier Ponds. This CM would 1) provide ecological enhancements to the channel and floodplain; 2) ameliorate the adverse water temperature, fish migration, and fish entrainment effects of the current hydrologic connection between the creek and the ponds; and 3) integrate public access and interpretation of natural resources and historical features within and along a portion of Coyote Creek on County Parks property.

This CM would construct a 6,500-foot reach of Coyote Creek channel and an associated, approximately 45-acre floodplain at Ogier Ponds. Buildout of this CM would result in the complete fill and discontinuation of Ponds 1 and 5 ~~one pond (i.e., Pond 1)~~ and the ~~partially~~ partial fill of Ponds 2 and 5 ~~two other ponds (i.e., Ponds 2 and 5)~~ that would otherwise remain operational. An earthen berm would be constructed to hydrologically disconnect the remaining ponds from the restored reach of Coyote Creek.

ES.6.2.4 Lower Cold Water Management Zone Restoration Evaluation[1]

Implementation of the Ogier Ponds CM is anticipated to improve habitat conditions for steelhead in the FCWMZ and potentially improve the function of the CWMZ downstream of Ogier Ponds. A geomorphic and habitat evaluation of Coyote Creek from Ogier Ponds to Metcalf Road would be conducted to describe existing channel conditions and habitat suitability for steelhead. This evaluation would include a detailed evaluation of flows and water temperatures post-construction within the reach from Ogier Ponds to Metcalf Road. Information gathered during this effort would be used to identify, describe, and design future restoration opportunities in Coyote Creek.

ES.6.2.5 Maintenance of the North Channel Reach ~~Extension~~

As part of the FOCP, Valley Water ~~is able to~~ split outlet flows from Anderson Reservoir into the North and South Channels of Coyote Creek. The North Channel is being ~~would be~~ restored to its historical creek alignment as part of the Project by extending the limits that were originally constructed as a part of FOCP, creating additional channel length through County Parks and private property, and reconnecting the channel to the Coyote Creek confluence with the South Channel downstream.

As part of the Project, the North Channel Reach would be maintained. Maintenance activities would include maintaining the constructed wetland bench, maintaining design flow capacity through the North Channel, and replacing restoration plantings, as needed.

ES.6.2.6 Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach

As part of the FOCP's Habitat Mitigation and Monitoring Plan, Valley Water will implement spawning gravel and rearing habitat improvements in the Live Oak Restoration Reach directly downstream of Anderson Dam to address the potential effects of reservoir dewatering and sediment deposition on spawning and rearing habitat from the FOCP and Project. During Seismic Retrofit construction, this effort includes the placement of gravel and maintenance of placed large woody debris to improve spawning habitat conditions. Spawning gravel placement would be integrated with the long-term Sediment Augmentation Program (Section ES 6.2.7 ~~4.2.7.)~~

ES.6.2.7 Sediment Augmentation Program

Valley Water would implement a Sediment Augmentation Program to address the effects of course sediment loss for steelhead habitat from creek banks and bed incision below Anderson Dam. Sediment augmentation activities would improve geomorphic processes that create and maintain steelhead habitat and reduce channel incision that is typical in Lower Coyote Creek downstream of the dam. This program would consist of placing up to 500 cubic yards of sediment in Coyote Creek ~~that was sourced from the dry Anderson Reservoir lakebed. The sediment would be placed in Coyote Creek~~ initially at the Live Oak Restoration Reach, and later at multiple locations downstream of Anderson Dam within the Live Oak Restoration Reach and Ogier Ponds restoration area as determined by adaptive management.

ES.6.2.8 Geomorphic Flows Plan

The Geomorphic Flows Plan would identify flow releases from Anderson Dam that would be integrated into Post-Construction Operations to provide additional support for biological features of steelhead critical habitat that are maintained by periodic high flows capable of inundating the floodplain, scouring substrate, mobilizing gravel, and supporting channel migration, as described in the high flows principles of the California Environmental Flows Framework (California Environmental Flows Framework 2021). The Geomorphic Flows Plan would interact with the other conservations measures to achieve the following physical channel maintenance objectives downstream of Anderson Dam: mobilize substrate, scour and transport fine sediments, maintain unembedded gravel, support gravel bar formation, reduce riparian vegetation encroachment, support formation of inset benches and floodplains, increase channel migration and bank erosion, and create and maintain a wider active channel and topographic diversity.

ES.6.2.9 Phase 2 Coyote Percolation Dam Fish Passage Enhancements

As part of the FOCP, ~~Valley Water~~ the Phase 1 Coyote Percolation Dam Fish Passage Enhancements are currently underway. The Phase 2 Coyote Percolation Dam Fish Passage Enhancement CM (Phase 2 Coyote Percolation Dam CM) would consist of constructing downstream channel modifications to facilitate upstream and downstream fish passage in a reach of Coyote Creek approximately 10.5 miles downstream of Anderson Dam. The objective of this effort is to improve fish passage conditions at Coyote Creek downstream of the Coyote Percolation Dam.

ES.6.2.10 Coyote Creek Facilities Plan

Valley Water would draft a Coyote Creek Facilities Plan that outlines strategies for the implementation of the following two primary components:

- **Laguna Seca Groundwater Remediation.** The plan as originally described in the FAHCE Settlement Agreement would evaluate alternatives to manage groundwater inflow from Coyote Creek. The goal is to allow flow releases from Anderson Dam to continue uninterrupted to the vicinity of Metcalf Ponds in a manner that protects other parties' properties and water rights.

- **Metcalf Ponds Stream Corridor Restoration.** The plan as originally described in the FAHCE Settlement Agreement would evaluate alternatives to isolate percolation ponds, quarry pits, and other structures from the active Coyote Creek channel in the vicinity of Metcalf Road to reestablish a free-flowing creek channel through this area.

Depending on the results of the feasibility assessments conducted for the Coyote Creek Facilities Plan as part of the Project, specific design and implementation methodologies for resultant proposed measures would be selected through the ongoing FAHCE AMP and implemented pursuant to the FHRP.

ES.6.2.11 Cherry Flat Reservoir Cooperative Operating Agreement

As part of the Project and in accordance with *Settlement Agreement* Section 6.4.2.1.4 (FAHCE 2003), Valley Water would undertake reasonable best efforts to develop and execute a cooperative agreement with the City of San José regarding the operation of Cherry Flat Reservoir on Upper Penitencia Creek to ensure that habitat upstream of Valley Water facilities are kept in good condition subject to the availability of water for releases from the reservoir.

ES.6.2.12 Payment of Santa Clara Valley Habitat Conservation Plan Impact Fees

The Project is a covered activity under the Santa Clara Valley Habitat Plan (VHP) (Santa Clara Valley Habitat Agency [SCVHA] 2012). Valley Water would apply for VHP coverage for Project ~~project~~ activities and would pay impact fees for Project ~~project~~ activities, including fees for effects on stream, wetland, riparian, and serpentine habitats. The SCVHA would then use those fees to acquire, preserve, manage, and restore populations of the covered species and the sensitive habitats that are impacted by the proposed Project.

ES.6.3 Construction Monitoring

Construction monitoring would be completed to conform with industry BMPs, comply with regulatory permit requirements, and document Project ~~project~~ effects on habitats and species in order to adaptively manage them.

The monitoring elements described herein specifically pertain to monitoring efforts that would be conducted during the Project's construction phase.

ES.6.3.1 Water Quality Monitoring

Valley Water would monitor specific water quality metrics: 1) water temperature, turbidity, pH, and dissolved oxygen (DO), 2) sediment deposition, and 3) suspended sediment.

Water Temperature, Turbidity, pH, and DO Monitoring. Water temperature, DO, turbidity, and pH have been monitored during FOCP as part of the Condition 2 Plan and will continue to be monitored throughout construction of the Project. The water quality monitoring procedures would be documented in a Water Quality Sampling ~~Valley Water will continue to monitor water temperature and DO in Coyote Creek and Anderson Reservoir.~~ In Coyote Creek, water temperature and DO would be evaluated within the FCWMZ to determine if conditions are suitable for rearing of *O. mykiss*. Water temperatures in Anderson Reservoir during the Seismic Retrofit construction (including the remaining pool, when at deadpool) would be monitored to assess trends in surface temperature of the water that would be the source of outflow to Coyote Creek until the Project is completed (Valley Water 2020c).

Sediment Deposition Monitoring. Valley Water prepared a Sediment Deposition Monitoring Plan in for FOCP, which would continue through construction of the Project. Sediment deposition monitoring would assess the impacts from sediment released during FOCP and Project construction on spawning habitat quantity and quality within the Coyote Creek FCWMZ (Valley Water 2020g).

Suspended Sediment Monitoring. Similarly, Valley Water would continue to implement the Sediment Monitoring Plan developed for the FOCP to continuously monitor turbidity and suspended sediment in Coyote Creek through completion of Project construction activities (Valley Water 2021d ~~2021e~~).

ES.6.3.2 Groundwater Monitoring

Valley Water's 2021 Groundwater Management Plan ~~(2023)~~ would continue to be implemented; this includes groundwater monitoring and monitoring groundwater-dependent habitat (e.g., riparian and wetland habitat). Groundwater assessments would also be carried to compare groundwater levels to existing water basin sustainability goals (Valley Water 2021b ~~2023a~~).

ES.6.3.3 Vegetation Monitoring

***Phytophthora* Management and Monitoring.** Valley Water would implement plans to prevent, avoid, and/or minimize the spread of *Phytophthora* infestations as a result of construction and ~~project~~ Project-related activities and carry out pathogen sampling in the Project Area (Valley Water 2020e, 2021c ~~2021d~~).

Wetland and Riparian Habitat Dryback Monitoring. Valley Water's Wetland and Riparian Habitat Dryback Monitoring Plan prepared for the FOCP would continue to be implemented throughout Project construction. The plan's focus is to monitor dryback conditions and visually assessing wetlands and riparian habitats due to modified flows in Coyote Creek (Valley Water 2020d).

Milkweed Monitoring. Valley Water would continue to implement the Milkweed Monitoring Plan that was developed for the FOCP through the completion of Project construction (Valley Water 2020b).

ES.6.3.4 Fisheries Monitoring

Fisheries monitoring ~~identified for the FOCP~~ will be implemented under several approaches until completion of the Project construction.

Valley Water's Fish Rescue and Relocation Plan includes monitoring suitability of conditions to support *O. mykiss* in the FCWMZ of Coyote Creek following reservoir dewatering, as well as fish rescue and relocation (Valley Water 2020a). The Water Temperature and Fisheries Monitoring Plan provides an approach to monitoring conditions in Coyote Creek to support *O. mykiss*, an approach to determine if stream temperatures warrant conducting additional fish rescue and relocation efforts outlined in the Fish Rescue and Relocation Plan, and data collection to support the Coyote Creek Stream Flow and Water Temperature Forecast Model (Valley Water 2020c).

~~The Fyke Trapping and Passive Integrative Transponder (PIT) Tag Monitoring Plan outlines methods to assess presence and densities of *O. mykiss* in the FCWMZ and to track outmigration through the system (Valley Water 2021b).~~

The Coyote Creek monitoring efforts described in these plans would include a migration study, ~~fyke trap monitoring,~~ environmental DNA monitoring, adult escapement monitoring, and spawning surveys. Other monitoring plans at Anderson Reservoir would include migration flow monitoring, juvenile rearing studies, and environmental DNA monitoring.

ES.6.3.5 Reptile Monitoring

Valley Water would continue to implement the Western Pond Turtle Monitoring Plan that was prepared for the FOCP (Valley Water 2020f). Monitoring efforts would continue in suitable habitat in the FCWMZ for the duration of Project construction to determine if a significant reduction in western pond turtle populations has occurred from Project construction.

ES.6.3.6 Terrestrial Animal Monitoring

Valley Water would continue to conduct surveys for several terrestrial animal species that occur during the FOCP. Such surveys include annual surveys for nesting bald eagles (*Haliaeetus leucocephalus*) and golden eagles (*Aquila chrysaetos*), and annual monitoring surveys at a pallid bat (*Antrozous pallidus*) roost near Anderson Dam. In addition, implementation of the FOCP *Crotch's Bumble Bee Avoidance Plan* (Valley Water 2024) would continue during Project construction, unless and until the Crotch's bumble bee is added to the VHP as a covered species.

ES.6.3.7 Invasive Species Monitoring and Control

The Invasive Species Monitoring and Control Plan prepared for the FOCP would continue to be implemented throughout Project construction. Target species include non-native fish, crayfish (*Cambaridae*), American bullfrog (*Lithobates catesbeianus*), and red-eared sliders (*Trachemys scripta*), as well as opportunistic removal of other non-native species (Valley Water 2020h).

ES.6.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

Following the completion of Seismic Retrofit components, post-construction operations of Anderson Reservoir would begin. Anderson Reservoir would be restored to its existing (unrestricted) capacity of 89,278 acre-feet and allowed to withstand a normal operational range of water levels in the reservoir. Storage of water would resume, with water originating from rainfall in the watershed, inflows from the Coyote Reservoir upstream, and imported water releases from the U.S. Bureau of Reclamation's San Felipe Division of the Central Valley Project. Reservoir releases would be made consistent with the FAHCE rule curves.

Reservoir Refilling and Inflow. During Year 6 of Project construction, following regulatory approvals, Valley Water would begin refilling the reservoir to prepare for post-construction operations. Inflow into Anderson Reservoir would come from three sources: 1) uncontrolled natural inflow from surrounding tributaries, 2) flows from Coyote Reservoir, and 3) if available, imported water could be transferred into Anderson Reservoir via the Cross Valley Pipeline and Anderson Force Main through the conveyance pipeline within the LLOW. Once the reservoir is refilled to operable levels, FAHCE operational rule curves would be implemented.

Reservoir Outflow and FAHCE Rule Curves. Following completion of the Seismic Retrofit construction, outflows from Anderson Reservoir would occur in four ways: (1) normal releases up to 170 ~~190~~ cfs to Coyote Creek via the LLOW's bypass pipeline, (2) releases up to 1,315 cfs to Coyote Creek through the 78-inch conveyance pipeline (and is the pipeline that facilitates bi-directional transfers of water between Anderson Reservoir and the raw water distribution system), (3) releases up to 5,300 cfs from the HLOW (in the event of an emergency), and (4) uncontrolled releases from the spillway.

Reservoir releases would be made consistent with the FAHCE rule curves. The FAHCE rule curves are intended to provide suitable spawning and rearing habitat within the Coyote Creek Watershed, providing adequate passage for adult steelhead and salmon to reach suitable spawning and rearing habitat, and for the out-migration of juveniles. The FAHCE rule curves would add operational criteria that benefit steelhead and salmon populations by providing winter base flows, pulse flows, and summer releases to support each steelhead life stage, as well as by providing a framework for ramping pulse flows and reservoir operations under low-flow conditions. The implementation of FAHCE rule curves would differ under dry-year, median-year, and wet-year conditions.

Imported Water Storage and Releases. Anderson Reservoir operations would allow for the storage of imported water from San Luis Reservoir in Anderson Reservoir, if available, in late winter and spring, while temperatures of imported water are still relatively cold, via the Cross Valley Pipeline and Anderson Force Main. Imported water may also be moved into Anderson Reservoir at other times of the year, if necessary, to avoid losing Valley Water supplies stored in San Luis Reservoir or in anticipation of a planned shutdown in the conveyance system from San Luis Reservoir to Santa Clara County. Imported water is also released directly to Coyote Creek at the CDL and Cross Valley Pipeline Extension.

ES.6.5 Anderson Dam Facilities Maintenance

Valley Water would maintain the newly retrofitted Anderson Dam, associated facilities, and other appurtenances as part of Valley Water's Dam Maintenance Program (DMP) and Pipeline Maintenance Program (PMP).

The DMP includes over 65 covered maintenance activities grouped into four categories and includes both routine and corrective maintenance actions. Routine, or preventive, maintenance consists of normal work performed on existing infrastructure to maintain its expected life cycle.

Corrective maintenance consists of the replacement of components or appurtenances that have failed to maintain the service of the infrastructure (Valley Water 2012).

The PMP addresses maintenance for several pipelines and pipeline facilities that Valley Water owns and/or maintains. The program establishes a process for conducting routine water conveyance system maintenance activities, including maintenance on pipelines, pump stations, blow offs, turnouts and vaults (Valley Water 2007).

ES.6.6 Post-Construction Conservation Measures Operations and Maintenance

Following construction, ongoing compliance monitoring would confirm the functionality and success of Conservation Measures, and adaptive management measures would be determined by the Adaptive Management Team. Any subsequent maintenance activities would be performed in accordance with the Valley Water SMP, or as part of the FAHCE AMP.

Imported Water Releases and Pipeline Maintenance. Pipeline maintenance for the Project would be conducted under Valley Water's PMP (see above).

Ogier Ponds Operations and Maintenance. The newly restored reach of Coyote Creek would be regularly monitored and adaptively managed for habitat quality and geomorphic stability. Water quality in Ogier Ponds would also by monitored; monitoring sensors would be inspected and maintained regularly.

Maintenance of the North Channel Reach ~~Extension~~. Long term maintenance and operation of the North Channel would be conducted under the SMP and in accordance with the DMP for the weirs. Following large flow events, Valley Water would monitor the North Channel to ensure that the channel was maintaining positive drainage and that debris was not accumulating within the channel.

Spawning Gravel and Sediment Augmentation Program Maintenance. Following large flow events, Valley Water would inspect sediment and gravel augmentation sites to determine if maintenance is required. Maintenance would include replacing spawning gravels or sediments within Coyote Creek between Anderson Dam and Ogier Ponds. Culverts and low flow crossings between the dam and Coyote Percolation Ponds would also be inspected and maintained after dam releases that exceed 500 cfs.

Phase 2 Coyote Percolation Dam Operations and Maintenance. The restored, roughened Coyote Creek channel would be inspected bi-annually, particularly after large flow events, for signs of reduced channel function, including compromised conveyance capacity, geomorphic instability, obstructions to fish passage, and overall reduced aquatic habitat quality. Maintenance activities may include periodic sediment removal, invasive plant removal, trimming and/or removal of vegetation that obstructs channel flows, replacement of roughness elements, repair of in-channel bio-engineered habitat enhancements (e.g., rootwads, stream barbs, overhanging banks), rock slope protection enhancements.

The current operational rules for the Coyote Percolation Dam would remain in place.

Phase 2 Coyote Percolation Dam and Fish Ladder Operations Plan (part of the Coyote Creek Facilities Plan). Valley Water would develop and implement an updated operations plan for the modified Coyote Percolation Dam Facility that maximizes the benefits provided the Phase 2

Coyote Percolation Dam Fish Passage Enhancement and provides for fish passage in all typical flow conditions.

Post-Construction Cross Valley Pipeline Extension Operation. To manage groundwater recharge and meet minimum flow targets downstream of Coyote Percolation Ponds, Valley Water would release imported water to the downstream end of the CWMZ via the Cross Valley Pipeline Extension. During post-construction operations, the Cross Valley Pipeline Extension would only be operated during severely dry years when releases from Anderson Reservoir are insufficient to maintain a wetted channel to the Cross Valley Pipeline Extension outfall.

ES.6.7 Post-Construction Project and FAHCE Adaptive Management Program

The FAHCE AMP, outlined in Chapter 6 of the FHRP in accordance with the FAHCE *Settlement Agreement* (FAHCE 2003), would guide post-construction adaptive management of Project flow operations, and all non-flow fish barrier remediation and habitat restoration Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. A Project-specific AMP (Appendix D) has been developed in accordance with the framework described in the FAHCE *Settlement Agreement* and FAHCE Program. Implementation of the Project and FAHCE AMP is designed to satisfy ~~the measurable objectives defined in~~ the FAHCE *Settlement Agreement* and the FAHCE Program ~~FHRP,~~ management objectives, and overall conservation objective for steelhead trout and Chinook salmon. The measurable objectives are designed to assure the long-term management and effectiveness of Project Conservation Measures to benefit steelhead and Chinook salmon as defined by the FAHCE Program management objectives.

The Project and FAHCE AMP includes four key elements: measurable objectives for steelhead and salmon fisheries and their habitats; compliance monitoring, validation monitoring, effectiveness monitoring, and long-term trend monitoring; adaptive actions that may be identified to remedy any continuing impairment of a beneficial use; and reporting.

ES.6.8 Avoidance and Minimization Measures

Valley Water would implement a range of standardized measures to avoid or minimize adverse effects on the environment.

ES.6.8.1 Best Management Practices

Valley Water would incorporate BMPs from its *Best Management Practices Handbook* (Valley Water 2014a) into the Project design and throughout Project implementation. For work in and near streams, Valley Water would also follow applicable BMPs included in the *2014–2023 Stream Maintenance Program Manual* (Valley Water 2014b ~~2019~~). The Project would also include other applicable Valley Water BMPs as well as ~~VHP conditions~~ applicable Stream Maintenance Program BMPs.

ES.6.8.2 Valley Habitat Plan Conditions

Valley Water would adhere to applicable VHP conditions, including 1, 3, 4, 5, 7, 8, 11, 12, 13, 17, 19, and 20 ~~and 5~~, and all applicable VHP AMMs, including the aquatic habitat AMMs from VHP

Table 6-2, throughout Project implementation. Valley Water would also pay applicable VHP impact fees for construction related impacts in the Project Area. All VHP conditions and AMMs would be incorporated into the construction documents (plans and specifications).

ES.7 Permits, Approvals, and Consultations

The Project EIR would be used by the federal, State, regional, and local regulatory agencies issuing permits, as well as for other agency approvals and consultations for the Project. Agencies that are expected to use the EIR for consultations, permitting decisions, and approvals that are expected to be required for the Project include:

- Federal agencies: FERC, NMFS, U.S. Army Corps of Engineers (USACE), USFWS, and U.S. Environmental Protection Agency (USEPA)
- State agencies: CDFW, DSOD, SWRCB, State Office of Historic Preservation (SHPO), and the San Francisco Bay Conservation and Development Commission (BCDC)
- Regional and local agencies: Bay Area Air Quality Management District, County of Santa Clara, City of San Jose, City of Morgan Hill, Regional Water Quality Control Board (RWQCB), SCVHA

ES.7.1 Water Rights Amendments

In May 2015, Valley Water submitted proposed water rights amendments, or Petitions for Change, to the SWRCB to address technical aspects of the water rights subject to the FAHCE *Settlement Agreement*. These Petitions are being updated. The amendments are intended to update the water rights held in the Coyote Creek Watershed consistent with FAHCE. Technical changes include correcting the locations of points of diversion and updating maps. The petitions also request that Valley Water's water rights licenses be amended to add Fish and Wildlife Preservation and Enhancement as a beneficial use of the diverted water. Chapter 5 of the FHRP supports the petitions as they propose modifying current operations to ensure that this beneficial use of water is achieved.

ES.8 Summary of Project Impacts and Mitigation Measures

Table ES-1 summarizes the impacts of the Project. For each impact considered to be significant, the table summarizes the recommended mitigation measures. **Table ES-1** is intended to summarize the Project impacts and mitigation measures that are described in detail in Chapter 3, *Environmental and Regulatory Setting and Impact Analysis*; please refer to that chapter for a complete discussion of impacts.

Table ES-1. Summary of Impacts and Mitigation Measures

Impact	Significance Determination	Mitigation Measure
Aesthetics		
Impact AES-1: Substantial damage to scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a State Scenic Highway	LTS	No mitigation required.
Impact AES-2: Substantial degradation of the existing visual character or quality of public views of the site and its surroundings	SU	Mitigation Measure AES-1: Replacement Trees on Santa Clara County Parkland Mitigation Measure AES-2: Visual Screening of Construction Staging Areas
Impact AES-3: Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area	LTSM	Mitigation Measure AES-3: Construction Lighting
Agriculture		
Impact AG-1: Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland) to non-agricultural use	LTS	No mitigation required.
Impact AG-2: Conflict with existing zoning for agricultural use or a Williamson Act contract	LTS	No mitigation required.
Air Quality		
Impact AQ-1: Conflict with or obstruct implementation of the applicable air quality plan	SU	Mitigation Measure AQ-1: Implement Construction Criteria Air Pollutants Reduction Measures
Impact AQ-2: A cumulatively considerable net increase of any criteria pollutant for which the Project region is non-attainment under an applicable federal or State ambient air quality standard	SU	Mitigation Measure AQ-1: Implement Construction Criteria Air Pollutants Reduction Measures Mitigation Measure AQ-2: Implement Construction Blasting Fugitive Dust Emissions Reduction Measure Mitigation Measure AQ-3: Implement BAAQMD Enhanced Construction BMPs

Impact	Significance Determination	Mitigation Measure
Impact AQ-3: Expose sensitive receptors to substantial pollutant concentrations	SU	Mitigation Measure AQ-1: Implement Construction Criteria Air Pollutants Reduction Measures Mitigation Measure AQ-2: Implement Construction Blasting Fugitive Dust Emissions Reduction Measure
Impact AQ-4: Other emissions adversely affecting a substantial number of people	LTS	No mitigation required.
Biological Resources—Fisheries Resources		
Impact FR-1: Have a substantial adverse effect, either directly, through habitat modifications, or through substantial interference with movement on any species identified as a candidate, sensitive, or special-status fish species in local or regional plans, policies, or regulations, or by CDFW, NMFS, or USFWS in the fisheries resources study area		
FR-1a: Central California Coast Steelhead	LTS	No mitigation required.
FR-1b: Chinook Salmon	LTS	No mitigation required.
FR-1c: Pacific Lamprey	LTS	No mitigation required.
FR-1d: Sacramento Hitch	LTS	No mitigation required.
FR-1e: Southern Coastal Roach	LTS	No mitigation required.
FR-1f: Longfin Smelt	LTS	No mitigation required.
FR-1g: White Sturgeon	LTS	No mitigation required.
FR-1h: Green Sturgeon (Southern Distinct Population Segment)	NI	No mitigation required.
FR-1i: Riffle Sculpin	LTS	No mitigation required.
Biological Resources – Wildlife and Terrestrial Resources		
Impact TERR-1: A substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW or USFWS Service		
TERR-1a: Special-Status Plants	LTSM	Mitigation Measure TERR-1a(1): Invasive Plant Management at Coyote Ridge ~~Valley Water's~~ Tiburon Paintbrush Populations

Impact	Significance Determination	Mitigation Measure
		Mitigation Measure TERR-1a(2): Implementation of Avoidance and Minimization Measures during Post-Construction Maintenance at Anderson Dam and Conservation Measures Facilities to Reduce the Potential for Introduction or Spread of *Phytophthora* Mitigation Measure TERR-1a(3): Special-Status Plant Survey in the Previously Unsurveyed Portions of the Seismic Retrofit Area Mitigation Measure TERR-1a(4): ~~Seed Collection and Creation of a New Population of~~ San Francisco Collinsia <u>Conservation Measures</u>
TERR-1b: Bay Checkerspot Butterfly, Monarch Butterfly, and Crotch's Bumble Bee	LTS	No mitigation required.
TERR-1c: California Tiger Salamander, California Red-Legged Frog, and Foothill Yellow-Legged Frog	LTSM	Mitigation Measure TERR-1c(1): Special-Status Species Avoidance and Minimization Measures During Year 6 Reservoir Dewatering Mitigation Measure TERR-1c(2): Nonnative Species Management in Upper Penitencia Creek Watershed
TERR-1d: ~~Western~~ <u>Northwestern</u> Pond Turtle	LTS	No mitigation required.
TERR-1e: Bald Eagle and Golden Eagle	LTSM	Mitigation Measure TERR-1e: Nesting Eagle Avoidance and Minimization Measures
TERR-1f: Tricolored Blackbird, Yellow Warbler, White-Tailed Kite, Northern Harrier, and Other Breeding Birds	LTS	No mitigation required.
TERR-1g: Nonbreeding special-status birds	LTSM	Mitigation Measure TERR-1g: Burrowing Owl Impact Avoidance

Impact	Significance Determination	Mitigation Measure
TERR-1h: Pallid Bat	SU	Mitigation Measure TERR-1h(1): Avoid Disturbance of the Cochrane Road Barn Roost Mitigation Measure TERR-1h(2): Evict Pallid Bats prior to Initiating Maternity-Season Disturbance near the Cochrane Road Barn Roost Mitigation Measure TERR-1h(3): Minimize Impacts on Pallid Bats Roosting Outside the Cochrane Road Barn Mitigation Measure TERR-1h(4): Provide Alternative Pallid Bat Maternity Roost Structures
TERR-1i: Other special-status mammals	LTS	No mitigation required.
TERR-1j: San Francisco Bay special-status species	LTSM	Mitigation Measure TERR-1j: Contribution to Baylands Predator Management <u>and High Tide Refugia Enhancement</u>
Impact TERR-2: A substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by CDFW or USFWS	LTSM	Mitigation Measure TERR-1a(2): Implementation of Avoidance and Minimization Measures during Post-Construction Maintenance at Anderson Dam and Conservation Measures Facilities to Reduce the Potential for Introduction or Spread of *Phytophthora*
Impact TERR-3: A substantial adverse effect on State or federally protected wetlands through direct removal, filling, hydrological interruption, or other means	LTSM	Mitigation Measure TERR-1a(2): Implementation of Avoidance and Minimization Measures during Post-Construction Maintenance at Anderson Dam and Conservation Measures Facilities to Reduce the Potential for Introduction or Spread of *Phytophthora*
Impact TERR-4: Interfere substantially with the movement of any native resident or migratory species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites	SU	Mitigation Measure TERR-1h(1): Avoid Disturbance of the Cochrane Road Barn Roost Mitigation Measure TERR-1h(2): Evict Pallid Bats prior to Initiating Maternity-Season Disturbance near the Cochrane Road Barn Roost

Impact	Significance Determination	Mitigation Measure
		Mitigation Measure TERR-1h(3): Minimize Impacts on Pallid Bats Roosting Outside the Cochrane Road Barn Mitigation Measure TERR-1h(4): Provide Alternative Pallid Bat Maternity Roost Structures
Impact TERR-5: Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance	NI	No mitigation required.
Impact TERR-6: Conflict with the provisions of an adopted Habitat Conservation Plan/Natural Community Conservation Plan, or other approved local, regional, or State Habitat Conservation Plan	LTS	No mitigation required.
Cultural Resources		
Impact CR-1: Cause a substantial adverse change in the significance of a built environment historical resource	LTS	No mitigation required.
Impact CR-2: Cause a substantial adverse change in the significance of an archaeological resource	LTSM	Mitigation Measure CR-1: Preconstruction Cultural Resources Awareness Training Mitigation Measure CR-2: Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided Mitigation Measure CR-3: Prepare a Monitoring and Unanticipated Discoveries Plan
Impact CR-3: Disturb human remains	LTSM	Mitigation Measure CR-1: Preconstruction Cultural Resources Awareness Training Mitigation Measure CR-2: Prepare a Data Recovery and Treatment Plan for Historical Resources that Cannot be Avoided Mitigation Measure CR-3: Prepare a Monitoring and Unanticipated Discoveries Plan

Impact	Significance Determination	Mitigation Measure
Energy		
Impact ENR-1: Result in a significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources	LTSM	Mitigation Measure AQ-1: Implement Construction Criteria Air Pollutants Reduction Measures Mitigation Measure GHG-1: Utilize Electrification and Renewable Fuels During Construction
Impact ENR-2: Conflict with or obstruct a State or local plan for renewable energy or energy efficiency	LTSM	Mitigation Measure AQ-1: Implement Construction Criteria Air Pollutants Reduction Measures Mitigation Measure GHG-1: Utilize Electrification and Renewable Fuels During Construction
Geology and Soils		
Impact GEO-1: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving rupture of a known earthquake fault	LTS	No mitigation required.
Impact GEO-2: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking	LTS	No mitigation required.
Impact GEO-3: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving liquefaction	LTS	No mitigation required.
Impact GEO-4: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving landslides	LTSM	Mitigation Measure GEO-1: Repair Landslides Caused by Construction Activities
Impact GEO-5: Result in substantial soil erosion or the loss of topsoil	LTS	No mitigation required.
Impact GEO-6: Located on a geologic unit or soil that is unstable, or that would become unstable as a result of the Project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse	LTS	No mitigation required.
Impact GEO-7: Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature	LTSM	Mitigation Measure GEO-2: Paleontological Initial Survey Mitigation Measure GEO-3: Paleontological Detailed Survey and Construction Monitoring Mitigation Measure GEO-4: Paleontological Discoveries Treatment Plan

Impact	Significance Determination	Mitigation Measure
Greenhouse Gas Emissions		
Impact GHG-1: Generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment	LTSM	Mitigation Measure GHG-1: Utilize Electrification and Renewable Fuels During Construction Mitigation Measure GHG-2: Purchase Carbon Offsets Prior to Construction
Impact GHG-2: Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases	LTSM	Mitigation Measure GHG-1: Implement Construction GHG Emissions Reduction Measures Mitigation Measure GHG-2: ~~Purchase Carbon Offsets~~ Offset GHG Emissions Prior to and During Construction
Hazards and Hazardous Materials		
Impact HAZ-1: Create a significant hazard to the public or the environment from the routine transport, use, or disposal of hazardous materials	LTS	No mitigation required.
Impact HAZ-2: Create a significant hazard to the public or the environment through reasonably foreseeable upset or accident conditions involving the release of hazardous materials	LTSM	Mitigation Measure HAZ-1: Construction and Grading Operations Dust Control Measures. Mitigation Measure HAZ-2: Track Out Control Measures for Roads from NOA-Containing Areas. Mitigation Measure HAZ-3: Traffic Control Measures within NOA-Containing Construction Areas. Mitigation Measure HAZ-4: Dust Control Measures During Earthmoving Activities. Mitigation Measure HAZ-5: Dust Control Measures During Tunneling Activities. Mitigation Measure HAZ-6: Separation of Rock Containing NOA.
Impact HAZ-3: Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within 0.25 mile of an existing or proposed school	LTSM	Mitigation Measure HAZ-1: Construction and Grading Operations Dust Control Measures. Mitigation Measure HAZ-2: Track Out Control Measures for Roads from NOA-Containing Areas.

Impact	Significance Determination	Mitigation Measure
		Mitigation Measure HAZ-3: Traffic Control Measures within NOA-Containing Construction Areas. Mitigation Measure HAZ-4: Dust Control Measures During Earthmoving Activities. Mitigation Measure HAZ-5: Dust Control Measures During Tunneling Activities. Mitigation Measure HAZ-6: Separation of Rock Containing NOA. Mitigation Measure HAZ-7: Soil Testing and Proper Disposal of Potentially Contaminated Soils
Impact HAZ-4: Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment	LTSM	Mitigation Measure HAZ-7: Soil Testing and Proper Disposal of Potentially Contaminated Soils.
Impact HAZ-5: Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan	LTSM	Mitigation Measure PS-1: Prepare and Implement Traffic Management Plan Mitigation Measure WF-1: Reduce Emergency Response and Evacuation Interference during Construction and Develop a Response and Evacuation Strategy ~~Emergency Action Plan~~
Impact HAZ-6: Create a significant hazard to construction workers or the public through exposure to Valley Fever during Construction Activities	LTSM (during construction) NI (during operations)	Mitigation Measure HAZ-1: Construction and Grading Operations Dust Control Measures. Mitigation Measure HAZ-2: Track Out Control Measures for Roads from NOA-Containing Areas. Mitigation Measure HAZ-3: Traffic Control Measures within NOA-Containing Construction Areas. Mitigation Measure HAZ-4: Dust Control Measures During Earthmoving Activities. Mitigation Measure HAZ-5: Dust Control Measures During Tunneling Activities.

Impact	Significance Determination	Mitigation Measure
Hydrology		
Impact HYD-1: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would:		
i. Result in substantial erosion or siltation on- or offsite	SU	Mitigation Measure WQ-1: Develop and Implement an In-Reservoir Construction Area Water Quality Monitoring and Protection Plan. ~~None available.~~
ii. Substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or offsite	LTS	No mitigation required.
iii. Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff	LTS	No mitigation required.
iv. Impede or redirect flood flows	LTS	No mitigation required.
Impact HYD-2: Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of dam failure	LTS	No mitigation required.
Impact HYD-3: In flood hazard, tsunami, or seiche zones, risk release of pollutants due to Project ~~project~~ inundation	LTS	No mitigation required.
Groundwater Resources		
Impact GW-1: Substantially decrease groundwater supplies or interfere substantially with groundwater recharge such that the Project may impede sustainable groundwater management of the basin	LTSM	Mitigation Measure GW-1: Provide Alternative Water Supplies
Impact GW-2: Violate groundwater water quality standards or substantially degrade groundwater quality	LTSM	Mitigation Measure GW-1: Provide Alternative Water Supplies Mitigation Measure GW-2: Perchlorate Best Management Practices
Impact GW-3: Conflict with or obstruct implementation of the San Francisco Bay Basin Plan groundwater provisions or the District's Groundwater Management Plan (GWMP)	LTSM	Mitigation Measure GW-1: Provide Alternative Water Supplies

Impact	Significance Determination	Mitigation Measure
Water Supply		
Impact WS-1: Substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years	LTS	No mitigation required.
Impact WS-2: Require or result in the relocation or construction of new or expanded water facilities, the construction of which could cause significant environmental effects	LTSM	Mitigation Measure GW-1: Provide Alternative Water Supplies Mitigation Measure GW-2: Perchlorate Best Management Practices
Water Quality		
Impact WQ-1: Impair beneficial uses of surface waters OR violate any applicable surface water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality OR conflict or obstruct implementation of a water quality control plan	SU	~~None Available.~~ Mitigation Measure GW-2: Perchlorate Best Management Practices Mitigation Measure WQ-1: Develop and Implement an In-Reservoir Construction Area Water Quality Monitoring and Protection Plan
Land Use		
Impact LU-1: Cause a significant environmental impact due to a conflict with any land use plan, policy, or regulation adopted for the purpose of avoiding or mitigating an environmental effect	LTS	No mitigation required.
Noise and Vibration		
Impact NOI-1: Generate a substantial temporary or permanent increase in ambient noise levels in the vicinity of the Project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies, or generation of substantial incremental increase in noise levels	SU	Mitigation Measure NOI-1: Implement Construction Noise Reduction Measures Mitigation Measure NOI-2: Implement Seismic Retrofit Construction Noise Reduction Measures Mitigation Measure NOI-3: Implement Ogier Ponds CM Construction Noise Reduction Measures
Impact NOI-2: Generate excessive groundborne vibration or groundborne noise levels	LTSM	Mitigation Measure NOI-4: Seismic Retrofit and Sediment Augmentation Program Construction Vibration Reduction ~~Measures~~ Mitigation Measure NOI-5: Implement Blasting Plan

Impact	Significance Determination	Mitigation Measure
Public Services		
Impact PS-1: Result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, or result in need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for fire protection	LTSM	Mitigation Measure PS-1: Prepare and Implement Traffic Management Plan Mitigation Measure WF-1: Reduce Emergency Response and Evacuation Interference during Construction and Develop a Response and Evacuation Strategy ~~Emergency Action Plan~~
Impact PS-2: Result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, or result in need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for police protection	LTSM	Mitigation Measure PS-1: Prepare and Implement Traffic Management Plan Mitigation Measure WF-1: Reduce Emergency Response and Evacuation Interference during Construction and Develop a Response and Evacuation Strategy ~~Emergency Action Plan~~
Recreation		
Impact REC-1a: Temporary increased use of neighboring land-based recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated	LTSM	Mitigation Measure REC-1: ~~Maintenance Reimbursement for~~ Funding and Implementation of Park Facility Improvements within the Coyote Creek Corridor ~~Closures During High Flow Events~~
Impact REC-1b: Permanent loss of recreational facilities resulting in substantial physical deterioration, or the acceleration of physical deterioration, of neighboring facilities.	LTS	No mitigation required.
Impact REC-2: Construction or expansion of recreational facilities which might have an adverse physical effect on the environment	LTS	No mitigation required.
Transportation		
Impact TR-1: Conflict with a program, plan, ordinance or policy addressing the circulation system, including transit, roadway, bicycle and pedestrian facilities	LTSM	Mitigation Measure REC-1: ~~Maintenance Reimbursement for~~ Funding and Implementation of Park Facility Improvements within the Coyote Creek Corridor ~~Closures During High Flow Events~~ Mitigation Measure PS-1: Prepare and Implement ~~Construction~~ Traffic Management Plan

Impact	Significance Determination	Mitigation Measure
Impact TR-2: Conflict with or be inconsistent with *CEQA Guidelines* Section 15064.3, subdivision (b)	LTS	No mitigation required.
Impact TR-3: Substantially increase hazards due to a geometric design feature or incompatible use	LTS	No mitigation required.
Impact TR-4: Inadequate emergency access	LTSM	Mitigation Measure PS-1: Prepare and Implement Traffic Management Plan Mitigation Measure WF-1: Reduce Emergency Response and Evacuation Interference during Construction and Develop a Response and Evacuation Strategy ~~Emergency Action Plan~~
Tribal Cultural Resources		
Impact TCR-1: Cause a substantial adverse change in the significance of a tribal cultural resource listed or eligible for listing in the California Register of Historical Resources or determined by Valley Water to be significant	LTSM	Mitigation Measure CR-1: Pre-construction Cultural Resources Awareness Training Mitigation Measure CR-2: Prepare a Data Recovery and Treatment Plan for Historical Resources that Cannot be Avoided Mitigation Measure CR-3: Prepare a Monitoring and Unanticipated Discoveries Plan
Utilities and Service Systems		
Impact UTL-1: Require or result in the replacement, relocation, or construction of new or expanded stormwater drainage, telecommunication, or electric power facilities, the construction or relocation of which could cause significant environmental effects	LTS	No mitigation required.
Impact UTL-2: Generate solid waste in excess of State or local standards, or in excess of the capacity of local infrastructure, otherwise impair the attainment of solid waste reduction goals, or fail to comply with federal, State, and local management and reduction statutes and regulations related to solid waste	LTS	No mitigation required.
Wildfire		
Impact WF-1: Exacerbate wildfire risks and expose Project occupants to pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire due to slope, prevailing winds, and other factors	LTS	No mitigation required.

Impact	Significance Determination	Mitigation Measure
Impact WF-2: Require the installation or maintenance of associated infrastructure that may exacerbate fire risk or that may result in temporary or ongoing impacts to the environment	LTS	No mitigation required.
Impact WF-3: Expose people or structures to significant risks, including downslope or downstream flooding or landslides, as a result of runoff, post-fire slope instability, or drainage changes	LTS	No mitigation required.
Impact WF-4: Expose people or structures, either directly or indirectly, to a significant risk of loss, injury, or death involving wildland fires	LTSM	Mitigation Measure WF-1: Reduce Emergency Response and Evacuation Interference during Construction and Develop a Response and Evacuation Strategy ~~Emergency Action Plan~~ Mitigation Measure PS-1: Prepare and Implement Traffic Management Plan

Key: LTS = less than significant; LTSM = less than significant with mitigation; SU = significant and unavoidable; NI = no impact

ES.8.1 Alternatives Evaluated in the Draft EIR

The purpose of the alternatives analysis in an EIR is to describe a range of reasonable alternatives to the Project that can feasibly attain most of the identified Project objectives but would reduce or avoid one or more of the Project's significant impacts.

ES.8.2 No Project Alternative

CEQA Guidelines Section 15126.5(e) requires an EIR to evaluate the No Project Alternative. The purpose of evaluating the No Project Alternative is "to allow decision makers to compare the impacts of approving the proposed project with the impacts of not approving the proposed project."

The No Project Alternative does not necessarily correspond strictly to existing conditions. Instead, the No Project Alternative must describe reasonably foreseeable conditions if the Project were not approved.

Under the No Project Alternative, the Project would not proceed, and existing (post-FOCP) environmental conditions and Valley Water operations would be maintained. Following completion of the FOCP (which includes construction of ADTP), the existing Anderson Dam would be left in place, eliminating Project construction and other Conservation Measures as described in the Project Description. FOCP construction AMMs, including imported water releases using chillers, if necessary, would not occur following FOCP construction. The liquefiable materials in the dam embankment and other materials vulnerable to seismic movement would not be removed and replaced. No increased outlet capacity would be accommodated; the maximum outfall would remain at 2,500 cfs (2,000 cfs from the newly constructed tunnel under the ADTP plus the existing outfall with 500 cfs of capacity). Because the No Project Alternative would not address seismic vulnerability, including potential deformation due to seismically induced liquefaction, the maximum water elevation would remain at the restricted level (i.e., deadpool) as ordered by FERC.

The No Project Alternative would not meet the Project purpose to seismically retrofit, maintain, and operate Anderson Dam and Reservoir to meet FERC and DSOD safety requirements, thereby allowing Valley Water to maximize water supply and related incidental benefits, while avoiding and minimizing environmental impacts of the implementation of those safety directives and requirements. It also would not meet the fundamental Project objective to seismically retrofit and maintain the dam so that Valley Water may continue to operate it at capacity consistent with providing groundwater recharge and protecting public safety. Furthermore, the No Project Alternative would not be feasible because it would conflict with the February 20, 2020, FERC Order, which directed Valley Water to "continue to work with all haste to design and secure the necessary permits and complete the design for the larger Anderson Dam Seismic Retrofit Project" and DSOD requirements to have the ability to lower the maximum storage by 10 percent in 7 days and the full content within 90 days, and that the spillway be able to contain the PMF. Although the No Project Alternative would not achieve Project objectives and is infeasible, because it would not comply with the FERC directive of February 20, 2020, and DSOD requirements; the No Project Alternative was retained because it is required by CEQA.

ES.8.3 Increased Dredge Alternative

The Increased Dredge Alternative would remove a larger volume of sediment from the Anderson Reservoir bed compared to the Project, but all other components of the Project would remain the same. The purpose of this alternative is to reduce temporary downstream turbidity impacts during the construction of the Project, which would result in significant unavoidable impacts to hydrology and water quality. By excavating a large amount of sediment from the reservoir bed and providing area for upstream sediment to settle and deposit, this alternative reduces downstream sediment transport and thereby meaningfully reduces the potential for increased temporary erosion and sediment transport during certain-sized storm events that may occur during the 7-year Project construction period.

The Increased Dredge Alternative is feasible and includes all the other elements as the Project, with a change only in removal of sediment from the reservoir bed starting 2 years prior to planned construction. It would meet the first Project objective, to seismically retrofit and maintain the dam so that Valley Water can continue to operate it at capacity. The Increased Dredge Alternative would reduce the magnitude of impacts of the Project related to turbidity and downstream sedimentation during the construction period because the sediment removal would reduce the volume of unconsolidated sediments in the area of the drawn down reservoir. However, the alternative would increase the severity of significant and unavoidable impacts associated with earth movement and truck trips including air quality, GHG emissions, and noise. It would also increase traffic impacts to local and regional roadways, as two additional years of excavation (1.4 million cy of material) and trucking (750 truck trips per day) would be needed. The alternative would significantly increase costs through additional hauling of materials. Thus, it would not fully achieve the Project objective to avoid and minimize the environmental effects of construction and operation.

ES.8.4 Anderson Dam Operated with FAHCE-Plus Modified Rule Curves (FAHCE-Plus Modified) Alternative

The FAHCE-Plus Modified Alternative was developed through consultation with the Project TWG, which includes State and federal resource agencies, to create an alternate regime of flow releases designed to increase and better diversify salmonid migration on Coyote Creek. The FAHCE-Plus Modified Alternative evolved from the FAHCE rule curves (evaluated as part of the Project in this EIR) and the FAHCE-Plus rule curves proposed for implementation in consultation with the AMT in Stevens Creek and Guadalupe Watersheds; they were included in the FAHCE FHRP, Appendix A to the FAHCE Final EIR (Valley Water 2023b ~~2023c~~).

As part of this alternative, as suggested by the NMFS during ESA technical assistance recommendations developed in consultation with the TWG, Valley Water would develop an Anderson Dam Operations Work Group (OWG) to discuss and provide updates on FAHCE-Plus Modified operations. The FAHCE-Plus Modified Alternative would retain all other components of the Project, except that the FAHCE-Plus Modified rule curve, rather than the FAHCE rule curve, would govern dam releases after completion of Project construction, including construction of all Conservation Measures, as described below.

The FAHCE-Plus Modified rule curves are intended to increase the benefit of reservoir releases for fisheries during key salmonid life stages. Based on hydrologic modeling outputs, the FAHCE-Plus rule curves for Coyote Creek combine concepts of the FAHCE flow measures (comprised generally of winter base flows, winter and spring migration period pulse flows, and summer cold water management releases) with an enhanced set of rules for spring attraction, safeguard, and outmigration pulse flows designed to maximize fish migration. The FAHCE-Plus Modified operational rules are similar to those for FAHCE, with the following modifications:

- ~~Summer base flow is adjusted to include a slight increase in temperature limits of summer cold water releases, still within the normal temperature range for steelhead rearing, to enhance summer rearing habitat. This allows a greater portion of the reservoir volume to be used to provide summer flows.~~
- FAHCE-Plus Modified rule curves contain differences in the timing and release of pulse flows compared to the FAHCE scenario. Generally, in Coyote Creek FAHCE-Plus Modified:
  - Expands the time window available for pulse releases to December 1 through/including May 31
  - Initiates higher magnitude and more frequent pulse flows compared to FAHCE intended to increase passage opportunities for adult steelhead by increasing water depths through critical riffles
  - Includes prioritization of attraction and outmigration pulse flows to aid in both up- and outmigration of steelhead, as well as late season outmigration specific pulse flows. In addition to attraction and outmigration pulse flows, a safeguard pulse flow (described in more detail below) is also initiated if triggers for the other pulse flows are not met by January 15, combined storage in Anderson and Coyote Reservoirs is above a certain threshold, and downstream flows are above a certain threshold of any given water year.
  - Adds a security pulse. If no pulse has been released by March 1 and other conditions are met, a security pulse flow may be released at the discretion of the OWG.

~~To accommodate increased magnitude, duration, and number of pulse flow releases under FAHCE-Plus Modified, the definition of the cold pool within Anderson Reservoir was also modified. The increases in pulse flow releases made prior to May 31 deplete cold water storage in Anderson reservoir to a greater degree than pulse flow releases under FAHCE. To expand the volume of the cold-water pool available for the summer cold water release program, FAHCE-Plus Modified revises the summer steelhead rearing period (May 31 to October 1) local cold water release temperature limitation for flows from the reservoir from 14 °C or less under FAHCE to 16 °C or less under FAHCE-Plus Modified. This increased reservoir release temperature restriction is based on modeling and observed water temperatures showing that releases with a temperature of 16 °C or less are typically sufficient to maintain temperatures of 18 °C or less throughout the FCWMZ and, after completion of the Ogier Ponds CM, throughout the CWMZ.~~

Flows under the FAHCE-Plus Modified Alternative compared to the original FAHCE-Plus flows differ by minor changes in pulse timing, frequency, a downstream flow trigger, and flow for the safeguard flow, which would occur in winter if conditions had not been met to release an attraction flow. FAHCE Plus Modified also uses the original FAHCE *Settlement Agreement* threshold of 14°C for calculating the cold pool volume. In addition, the FAHCE-Plus Modified rule curves ~~provide~~ retain the longer pulse flow duration and increased volume of pulse flow from FAHCE Plus, with an increase in number of years with a pulse flow, and an increase in the number of pulses to comprise attraction, outmigration pulse and safeguard pulses ~~pulsed~~

through the period December 1 to May 31, and variations to the length of each type of pulse under some conditions in order to provide a diversity in migratory opportunity.

Because the FAHCE-Plus Modified Alternative includes the same non-rule curve elements as the Project and is a feasible alternative, it would meet the first Project objective, to seismically retrofit and maintain the dam so that Valley Water can continue to operate it at capacity. In addition, this alternative would meet the objectives to improve cost efficiency of dam operations and avoid and minimize impacts. This alternative would not reduce any significant impacts of the Project; it was selected for detailed consideration because it would improve outcomes for anadromous fish.

ES.8.5 Modification of Ogier Ponds Lands West of Pond 1 and Pond 2 to Protect Ponds and to Avoid Trucking (Ogier Ponds Alternative)

The Ogier Ponds Alternative would retain all components of the Project; however, the Ogier Ponds CM would be modified (Valley Water 2023). The Ogier Ponds Alternative includes excavating a new channel for Coyote Creek with associated floodplain, habitat area, and separation berm, in the agricultural field west of Pond 1 and reestablishing the Coyote Creek alignment that was originally constructed by Santa Clara County Parks and Recreation Department at the close of gravel mining activities. This alternative would avoid the ~~partial~~ filling of Ponds 1 and 5 and partial filling of Pond 2, as would be done under the Ogier Ponds CM. Under both the Ogier Ponds CM and this alternative, Pond 4 ~~Ponds 2 and 5~~ would be partially filled.

Implementation of this alternative would require Valley Water to acquire property rights from up to nine ~~six~~ private property owners. The timeline for acquisition of these property rights is uncertain and could result in schedule delays. However, this effort would not affect the schedule for implementation of the Seismic Retrofit components. Accordingly, it would not result in increased risks to public health and safety related to seismic vulnerabilities of the dam, and the schedule uncertainties would not affect the feasibility of this alternative.

ES.8.6 Comparison of Proposed Project and Alternative Impacts

Table ES-2 summarizes impacts of the alternatives and compares proposed Project impacts with the impacts of each of the alternatives evaluated in the EIR. Direct Project impacts fall into the following categories (Chapter 3 also evaluates whether each of these impacts is cumulatively considerable):

- No impact (NI)
- Less-than-significant impact (LTS)
- Less-than-significant impact with mitigation (LTSM)
- Significant and unavoidable impact (SU); no feasible mitigation measures are available to reduce impacts to a less-than-significant level

Table ES-2 also compares the magnitude of impacts of the alternatives to those of the proposed Project, with a “+” indicating that the alternative would have a greater adverse impact than the proposed Project, a “-” indicating that the alternative would have a less adverse impact than the proposed Project, and an “=” indicating that the alternative would have the same level of impact as the proposed Project.

1 **Table ES-2. Summary of Impacts for the Project and for Alternatives Evaluated in the Draft EIR**

Impact	Level of Impacts with Mitigation				
	Project	**No Project**	**Increased Dredge**	**FAHCE-Plus Modified ~~Enhanced~~**	**Ogier Ponds**
Aesthetics					
Impact AES-1: Substantial damage to scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a State Scenic Highway	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact AES-2: Substantial degradation of the existing visual character or quality of public views of the site and its surroundings	SU	SU (+)	SU (+)	SU (=)	SU (=)
Impact AES-3: Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (=)
Agricultural and Forestry Resources					
Impact AG-1: Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use	LTS	NI (-)	LTS (=)	LTS (=)	SU (+)
Impact AG-2: Conflict with existing zoning for agricultural use or a Williamson Act contract	LTS	NI (-)	LTS (=)	LTS (=)	LTS (+)
Air Quality					
Impact AQ-1 ~~AIR-1~~: Conflict with or obstruct implementation of the applicable air quality plan	SU	NI (-)	SU (+)	SU (=)	SU (-)
Impact AQ-2 ~~AIR-2~~ Cumulatively considerable net increase of any criteria pollutant for which the Project region is non-attainment under an applicable federal or State ambient air quality standard	SU	NI (-)	SU (+)	SU (=)	SU (-)
Impact AQ-3: Expose sensitive receptors to substantial pollutant concentrations	SU	NI (-)	SU (+)	SU (=)	SU (-)
Impact AQ-4: Other emissions adversely affecting a substantial number of people	LTS	NI (-)	LTS (+)	LTS (=)	LTS (-)
Biological Resources – Fisheries Resources					
Impact FR-1: Have a substantial adverse effect, either directly, through habitat modifications, or through substantial interference with movement on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW, NMFS, or USFWS in the fisheries resources study area					

Impact	Level of Impacts with Mitigation				
	Project	No Project	Increased Dredge	FAHCE-Plus Modified ~~Enhanced~~	Ogier Ponds
FR-1a: Central California Coast Steelhead	LTS	SU (+)	LTS (+)	LTS (=)	LTS (=)
FR-1b: Chinook Salmon	LTS	SU (+)	LTS (+)	LTS (=)	LTS (=)
FR-1c: Pacific Lamprey	LTS	SU (+)	LTS (+)	LTS (=)	LTS (=)
FR-1d: Sacramento Hitch	LTS	SU (+)	LTS (+)	LTS (=)	LTS (=)
FR-1e: Southern Coastal Roach	LTS	SU (+)	LTS (+)	LTS (=)	LTS (=)
FR-1f: Longfin Smelt	LTS	NI (-)	LTS (+)	LTS (=)	LTS (=)
FR-1g: White Sturgeon	LTS	NI (-)	LTS (+)	LTS (=)	LTS (=)
FR-1h: Green Sturgeon	NI	NI (=)	NI (=)	NI (=)	NI (=)
FR-1i: Riffle Sculpin	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Biological Resources – Wildlife and Terrestrial Resources					
Impact TERR-1: Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW or USFWS					
TERR-1a: Special-Status Plants	LTSM	LTS (-)	LTSM (+)	LTSM (=)	LTSM (-)
TERR-1b: Bay Checkerspot Butterfly, Monarch Butterfly, and Crotch's Bumble Bee	LTS	NI (-)	LTS (=)	LTS (=)	LTS (-)
TERR-1c: California Tiger Salamander, California Red-Legged Frog, and Foothill Yellow-Legged Frog	LTSM	SU (+)	LTSM (=)	LTSM (=)	LTSM (-)
TERR-1d: ~~Western~~ Northwestern Pond Turtle	LTS	SU (+)	LTS (=)	LTS (=)	LTS (-)
TERR-1e: Bald Eagle and Golden Eagle	LTSM	LTS (-)	LTSM (+)	LTSM (=)	LTSM (=)
TERR-1f: Tricolored Blackbird, Yellow Warbler, White-tailed Kite, Northern Harrier, and Other Breeding Birds	LTS	NI (-)	LTS (=)	LTS (=)	LTS (-)
TERR-1g: Nonbreeding Special-Status Birds	LTSM	NI (-)	LTSM (=)	LTSM (=)	LTSM (-)
TERR-1h: Pallid Bat	SU	NI (-)	SU (=)	SU (=)	SU (=)
TERR-1i: Other Special-Status Mammals	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
TERR-1j: San Francisco Bay Special-Status Species	LTSM	NI (-)	LTSM (=)	LTSM (=)	LTSM (=)

Impact	Level of Impacts with Mitigation				
	Project	No Project	Increased Dredge	FAHCE-Plus Modified ~~Enhanced~~	Ogier Ponds
Impact TERR-2: Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by CDFW or USFWS	LTSM	SU (+)	LTSM (=)	LTSM (=)	LTSM (-)
Impact TERR-3: Have a substantial adverse effect on State or federally protected wetlands through direct removal, filling, hydrological interruption, or other means	LTSM	SU (+)	LTSM (=)	LTSM (=)	LTSM (-)
Impact TERR-4: Interfere substantially with the movement of any native resident or migratory species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites	SU	SU (+)	SU (=)	SU (=)	SU (=)
Impact TERR-5: Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance	NI	NI (-)	NI (=)	NI (=)	NI (=)
Impact TERR-6: Conflict with the provisions of an adopted Habitat Conservation Plan/Natural Community Conservation Plan, or other approved local, regional, or State habitat conservation plan	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Cultural Resources					
Impact CR-1: Cause a substantial adverse change in the significance of a built environment historical resource	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact CR-2: Cause a substantial adverse change in the significance of an archaeological resource	LTSM	LTS (-)	LTSM (+)	LTSM (=)	LTSM (+)
Impact CR-3: Disturb Human Remains	LTSM	LTS (-)	LTSM (+)	LTSM (=)	LTSM (+)
Energy					
Impact ENR-1: Result in a significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (-)
Impact ENR-2: Conflict with or obstruct a State or local plan for renewable energy or energy efficiency	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (-)
Geology and Soils					
Impact GEO-1: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving rupture of a known earthquake fault	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)

Impact	Level of Impacts with Mitigation				
	Project	No Project	Increased Dredge	FAHCE-Plus Modified ~~Enhanced~~	Ogier Ponds
Impact GEO-2: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact GEO-3: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving liquefaction	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact GEO-4: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving landslides	LTSM	NI (-)	LTSM (=)	LTSM (=)	LTSM (=)
Impact GEO-5: Result in substantial soil erosion or the loss of topsoil	LTS	NI (-)	LTS (+)	LTS (=)	LTS (=)
Impact GEO-6: Located on a geologic unit or soil that is unstable, or that would become unstable as a result of the Project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact GEO-7: Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (+)
Greenhouse Gas Emissions					
Impact GHG-1: Generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (-)
Impact GHG-2: Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (-)
Hazards and Hazardous Materials					
Impact HAZ-1: Create a significant hazard to the public or the environment from the routine transport, use, or disposal of hazardous materials	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact HAZ-2: Create a significant hazard to the public or the environment through reasonably foreseeable upset or accident conditions involving the release of hazardous materials into the environment	LTSM	NI (-)	LTS (=)	LTSM (=)	LTSM (=)
Impact HAZ-3: Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school	LTSM	NI (-)	LTS (=)	LTSM (=)	LTSM (=)

Impact	Level of Impacts with Mitigation				
	Project	**No Project**	**Increased Dredge**	**FAHCE-Plus Modified ~~Enhanced~~**	**Ogier Ponds**
Impact HAZ-4: Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment	LTSM	NI (-)	LTSM (=)	LTSM (=)	LTSM (+)
Impact HAZ-5: Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (=)
Impact HAZ-6: Create a significant hazard to construction workers or the public through exposure to Valley Fever during Construction Activities	LTSM	NI (-)	LTSM (=)	LTSM (=)	LTSM (=)
Hydrology					
Impact HYD-1i: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner which would result in substantial erosion or siltation on- or off-site	SU	SU (+)	SU (-)	SU (=)	SU (=)
Impact HYD-1ii: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or offsite	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact HYD-1iii: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact HYD-1iv: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would impede or redirect flood flows	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact HYD-2: Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of dam failure	LTS	SU (+)	LTS (=)	LTS (=)	LTS (=)

Impact	Level of Impacts with Mitigation				
	Project	No Project	Increased Dredge	FAHCE-Plus Modified ~~Enhanced~~	Ogier Ponds
Impact HYD 3: In flood hazard, tsunami, or seiche zones, risk release of pollutants due to Project inundation	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Groundwater Resources					
Impact GW-1: Substantially decrease groundwater supplies or interfere substantially with ground-water recharge such that the Project may impede sustainable groundwater management of the basin	LTSM	SU (+)	LTSM (=)	LTSM (=)	LTSM (=)
Impact GW-2: Violate groundwater water quality standards or substantially degrade groundwater quality	LTSM	NI (-)	LTSM (=)	LTSM (=)	LTSM (=)
Impact GW-3: Conflict with or obstruct implementation of the San Francisco Bay Basin Plan groundwater provisions or the District's GWMP	LTSM	SU (+)	LTSM (=)	LTSM (=)	LTSM (=)
Water Supply					
Impact WS-1: Substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years	LTS	SU (+)	LTS (=)	LTS (=)	LTS (=)
Impact WS-2 ~~GW-2~~: Require or result in the relocation or construction of new or expanded water facilities, the construction of which could cause significant environmental effects	LTSM	SU (+)	LTSM (=)	LTSM (=)	LTSM (=)
Water Quality					
Impact WQ-1: Impair beneficial uses of surface waters OR violate any applicable surface water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality OR conflict or obstruct implementation of a water quality control plan	SU	SU (+)	SU (-)	SU (=)	SU (=)
Land Use and Planning					
Impact LU-1: Cause a significant environmental impact due to a conflict with any land use plan, policy, or regulation adopted for the purpose of avoiding or mitigating an environmental effect	LTS	NI (-)	LTS (=)	LTS (=)	LTS (+)

Impact	Level of Impacts with Mitigation				
	Project	No Project	Increased Dredge	FAHCE-Plus <u>Modified</u> ~~Enhanced~~	Ogier Ponds
Noise and Vibration					
Impact NOI-1: Generate a substantial temporary or permanent increase in ambient noise levels in the vicinity of the Project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies, or generation of substantial incremental increase in noise levels	SU	NI (-)	SU (+)	SU (=)	SU (=)
Impact NOI-2: Generate excessive groundborne vibration or groundborne noise levels	LTSM	NI (-)	LTSM (=)	LTSM (=)	LTSM (=)
Public Services					
Impact PS-1: Result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, or result in need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for fire protection	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (=)
Impact PS-2: Result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, or result in need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for police protection	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (=)
Recreation					
Impact REC-1a: Temporary increased use of neighboring recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated	LTSM	SU (+)	LTSM (=)	LTSM (=)	LTSM (=)
Impact REC-1b: Permanent loss of recreational facilities resulting in substantial physical deterioration, or the acceleration of physical deterioration, of neighboring facilities	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact REC-2: Construction or expansion of recreational facilities which might have an adverse physical effect on the environment	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Transportation					
Impact TR-1: Conflict with a program, plan, ordinance or policy addressing the circulation system, including transit, roadway, bicycle and pedestrian facilities	LTSM	SU(+)	LTSM (=)	LTSM (=)	LTSM (=)

Impact	Level of Impacts with Mitigation				
	Project	**No Project**	**Increased Dredge**	**FAHCE-Plus Modified ~~Enhanced~~**	**Ogier Ponds**
Impact TR-2: Conflict with or be inconsistent with *CEQA Guidelines* Section 15064.3, subdivision (b)	LTS	NI (-)	LTS (=)	LTS (=)	LTS (-)
Impact TR-3: Substantially increase hazards due to a geometric design feature or incompatible use	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact TR-4: Inadequate emergency access	LTSM	NI (-)	LTSM (+)	LTSM (=)	LTSM (=)
Tribal Cultural Resources					
Impact TCR-1: Cause a substantial adverse change in the significance of a tribal cultural resource listed or eligible for listing in the California Register of Historical Resources or determined by Valley Water to be significant	LTSM	LTS (-)	LTSM (+)	LTSM (=)	LTSM (=)
Utilities and Service Systems					
Impact UTL-1: Require or result in the replacement, relocation, or construction of new or expanded stormwater drainage, telecommunication, or electric power facilities, the construction or relocation of which could cause significant environmental effects	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact UTL-2: Generate solid waste in excess of State or local standards, or in excess of the capacity of local infrastructure, otherwise impair the attainment of solid waste reduction goals, or fail to comply with federal, State, and local management and reduction statutes and regulations related to solid waste	LTS	NI (-)	LTS (=)	LTS (=)	LTS (+)
Wildfire					
Impact WF-1: Exacerbate wildfire risks and expose Project occupants to pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire due to slope, prevailing winds, and other factors	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact WF-2: Require the installation or maintenance of associated infrastructure that may exacerbate fire risk or that may result in temporary or ongoing impacts to the environment	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)
Impact WF-3: Expose people or structures to significant risks, including downslope or downstream flooding or landslides, as a result of runoff, post-fire slope instability, or drainage changes	LTS	NI (-)	LTS (=)	LTS (=)	LTS (=)

Impact	**Level of Impacts with Mitigation**				
	Project	**No Project**	**Increased Dredge**	**FAHCE-Plus Modified ~~Enhanced~~**	**Ogier Ponds**
Impact WF-4: Expose people or structures, either directly or indirectly, to a significant risk of loss, injury, or death involving wildland fires	LTSM	NI (-)	LTSM (=)	LTSM (=)	LTSM (=)

Key: LTS = less than significant; LTSM = less than significant with mitigation; SU = significant and unavoidable; NI = no impact

ES.8.7 Environmentally Superior Alternative

CEQA Guidelines Section 15126.6(e)(2) requires the identification of an environmentally superior alternative to the proposed Project. If the environmentally superior alternative is the no project alternative, the EIR shall also identify an environmentally superior alternative among the action alternatives. For this EIR, the No Project Alternative is not considered environmentally superior. Although it avoids some of the Project's significant impacts, as shown in **Table ES-2** ~~**Table 5-8**~~, it creates new significant and unavoidable impacts for many important resources, including fisheries resources, wildlife and terrestrial resources, hydrology, water quality, groundwater, water supply and recreation. It also would not meet the Project purpose and fundamental Project objectives.

Of the alternatives considered in the EIR, the FAHCE-Plus Modified Alternative is considered the environmentally superior alternative. This alternative achieves all the Project objectives and provides more benefits than the Project for special-status fish species, specifically for steelhead, Chinook, and Pacific lamprey, southern coastal roach, and Sacramento hitch, thus better achieving the Project objective to avoid and minimize environmental impacts. It also does not cause new or worse significant impacts as compared to the Project.

ES.9 Areas of Known Controversy

CEQA Guidelines Section 15123 states that an EIR must identify areas of known controversy that might have been raised by other agencies, the public, or other stakeholders. Areas of communicated controversy related to the EIR identified in the EIR scoping process include, but are not limited to, the following:

- Project Duration: Many public commenters over the years have expressed concerns about length of the Project ~~project~~ and length of the impacts associated with construction.
- Coordination with FAHCE: The FAHCE program covers aspects of adaptive management for Coyote Creek. While the FAHCE Final Program EIR was certified by Valley Water’s Board of Directors on August 8, 2023, comments were made by stakeholders regarding the adequacy of the program.

Areas of communicated controversy identified during public review of the Draft EIR and Partially Recirculated Draft EIR include:

- Air quality impacts, including dust and health risk, at nearby residential uses during construction.
- Increased noise from construction and construction traffic, as well as nighttime construction noise.
- Length of park closures.
- Increased wildfire risk during construction
- Emergency access and impairment of evacuation routes.

ES.10 Issues to be Resolved

CEQA Guidelines Section 15123 calls for the lead agency to disclose issues to be resolved, including the choice among alternatives and whether or how to mitigate significant effects. Issues to be resolved related to the proposed Project or EIR include, but are not limited to, the following:

- Securing access rights to Santa Clara County-owned parkland for the construction and maintenance of the Seismic Retrofit and Conservation Measures
- Securing access rights to privately owned land for the construction and maintenance of Seismic Retrofit Project and Conservation Measures
- Timely completion of the Coyote Creek Flood Protection Project prior to the start of Project dam embankment construction
- Choice of EIR alternatives and how to mitigate significant environmental impacts.

ES.11 Stakeholder Coordination and Public Involvement Process

ES.11.1 Stakeholder Coordination and Engagement Process

Valley Water has coordinated and engaged with a number of stakeholders, including regulatory agencies, Tribal representatives, and the public, outside of the formal CEQA scoping process since 2013. Valley Water has hosted interagency meetings on at least a quarterly basis since 2018 to discuss the Project, and these meetings will continue throughout the Project. Agencies represented at these meetings include FERC Division of Hydropower Administration and Compliance (FERC DHAC), FERC Division of Dam Safety and Inspections, USFWS, NMFS, CDFW, USACE, SWRCB, RWQCB, USEPA, SCVHA, SHPO, and Santa Clara County Department of Parks and Recreation. Technical and executive working groups were formed with that included most of these agencies.

Outreach with tribal representatives began in 2018 and has been advancing under the FOCP Programmatic Agreement between FERC DHAC and the SHPO.

Additionally, Valley Water has held public information meetings at least once per year since 2017 and began holding public meetings twice per year in 2020, in response to the FERC Order, and to keep the public informed about the advancement of the Project.

ES.11.2 EIR Scoping

Valley Water circulated a Notice of Preparation and Initial Study for the Project on August 13, 2013. Although not specifically required by CEQA, Valley Water held an informational public scoping meeting on August 26, 2013. A scoping report, which includes the NOP and comments received in response to the NOP and at the scoping meeting, is included in this ~~Draft~~ Final EIR as Appendix B, *Notice of Preparation/Initial Study and Scoping Report*.

ES.11.3 Draft EIR Public Comment Period

On September 1, 2023, Valley Water ~~has~~ issued a Notice of Availability of the Draft EIR to provide agencies and the public with formal notification that the Draft EIR ~~is~~ was available for review and comment. The Notice of Availability, Draft EIR, and selected appendices ~~are~~ were made available at the following website: www.valleywater.org/ADSRP. Copies of the Draft EIR and appendices ~~are~~ were also made available for review at the following locations:

- Valley Water, 5750 Almaden Expressway, San José, California 95118-3686
- City of Morgan Hill, 17575 Peak Avenue, Morgan Hill, California 95037
- City of Morgan Hill Library, 60 West Main Avenue, Morgan Hill, California 95037

Valley Water ~~is circulating this~~ circulated the Draft EIR for a 68-day ~~60-day~~ public review and comment period between September 1 and November 8, 2023~~. and will host a public meeting to receive public comments during this period.~~ The public meeting for the Draft EIR ~~is scheduled for~~ was held on October 4, 2023, from 6:30 p.m. to 8:00 p.m. at the Morgan Hill Community and Cultural Center.

~~Written comments concerning this Draft EIR should be mailed or emailed during this review period and should be directed to the name and address listed below. Please submit your response at the earliest possible date, but no later than 60 days from release of the Draft EIR on September 1, 2023, on November 1, 2023.~~

~~Tiffany Chao, Senior Environmental Planner~~
~~Santa Clara Valley Water District~~
~~5750 Almaden Expressway~~
~~San José, California 95118-3686~~
~~(408) 630-3107~~
~~ADSRPcomments@valleywater.org~~

~~Written comments received on the Draft EIR will be addressed in the Final EIR.~~

Valley Water received a total of 90 comment letters or other written documents, such as emails on the Draft EIR, before the close of the public review and comment period. Written comments received on the Draft EIR are included and responded to in Chapter 7 of this Final EIR. Additionally, 34 letters related to EIR contents were received related to the separate FERC petition process associated with the Project during the Draft EIR public review and comment period. These 34 FERC-related letters are addressed in Chapter 7, although they were not submitted as Draft EIR comment letters and therefore no responses were required under CEQA.

ES.11.4 Partially Recirculated Draft EIR Public Comment Period

After circulation of the Draft EIR, Valley Water met with the Project Board of Consultants (BOC), which reviews the Project and makes recommendations to FERC, to discuss updated design plans and construction sequencing. In response to that meeting and BOC recommendations, Valley Water made certain construction changes such as extending work hours, adding some weekend days, and beginning work on certain Project components sooner. These proposed changes would allow Valley Water to construct planned Project components within the planned construction timeline before the wet season each year to improve its ability to complete the Project on schedule.

These Project changes necessitated revisions to certain impact analyses in the aesthetics, air quality, greenhouse gas emissions, and noise and vibration sections of the Draft EIR, as well as associated technical appendices, which were included in a Partially Recirculated Draft EIR.

On August 5, 2024, Valley Water issued a Notice of Availability of the Partially Recirculated Draft EIR to provide agencies and the public with formal notification that the Partially Recirculated Draft EIR was available for review and comment. The Notice of Availability, Partially Recirculated Draft EIR, and selected appendices were made available at the following website: https://www.valleywater.org/public-review-documents. Copies of the Partially Recirculated Draft EIR and appendices were also available for review at the following locations:

- Valley Water, 5750 Almaden Expressway, San José, California 95118-3686
- City of Morgan Hill, 17575 Peak Avenue, Morgan Hill, California 95037
- City of Morgan Hill Library, 60 West Main Avenue, Morgan Hill, California 95037

Valley Water circulated the Partially Recirculated Draft EIR for a 45-day public review and comment period between August 5 and September 20, 2024.

Valley Water received a total of 11 comment letters or other written documents such as emails on the Partially Recirculated Draft EIR before the close of the public review and comment period. Written comments received on the Partially Recirculated Draft EIR are included and responded to in Chapter 8 of this Final EIR.

ES.11.5 Preparation of Final Environmental Impact Report and Project Approval Process

The Final EIR consists of a comprehensive revision to the EIR that occurred after public circulation of the Draft EIR and Partially Recirculated Draft EIR (including technical appendices), public comments on the Draft EIR and Partially Recirculated Draft EIR received during public review periods, and responses to the public comments. Revisions include the following:

- Updates to the Project description to replace construction of the North Channel Extension with the Maintenance of the North Channel Reach
- Changes to the Ogier Ponds Conservation Measure
- Refinements to the Sediment Augmentation Program,
- Refinements to the number of construction and haul trips
- Changes to the temporary trail closures
- Changes to the construction sequencing of the Phase 2 Coyote Percolation Dam CM,
- Clarifications of the construction phase monitoring
- Other minor changes and corrections.

Changes to the Project description are reflected in revised modeling for air quality, greenhouse gasses, energy, and noise and vibration. In addition, minor changes and clarifications were made to the FAHCE-Plus Modified Alternative description and impact analysis.

Some of the Chapter 3 impact analyses and mitigation measures were revised to reflect changes in the Project description to address public and regulatory agency Draft EIR comments, and to increase accuracy, but impact significance conclusions remained the same. Preparation of a Water Quality Monitoring and Protection Plan was added as new Mitigation Measure WQ-1 to reduce significant unavoidable water quality and erosion impacts related to in-reservoir construction that were identified in the Draft EIR. Mitigation Measure REC-1 was refined based on Draft EIR comments and coordination with Santa Clara County. The wildfire impact analysis and Mitigation Measure WF-1 were refined in response to Draft EIR comments and additional public input. Additionally, Mitigation Measure GHG-1 was refined to provide flexibility in offsetting greenhouse gas emissions. Mitigation Measure NOI-3 was refined based on the revised noise analysis which was updated based on Project Description changes.

All written comments received on the adequacy of the Draft EIR and Partially Recirculated Draft EIR during the public review periods are addressed in “response to comments” chapters in this Final EIR (Chapters 7 and 8). The response to comments and Final EIR also presents changes to the EIR resulting from public and agency comments, and Valley Water staff-initiated changes. Text changes to the Draft EIR or Recirculated Draft EIR are shown in this Final EIR in underline (new text added) and ~~strikeout~~ (deleted text) format. Occasional changes to figures are shown by inserting new figures and striking out the prior figures. Appendices are not included in underline and strikeout to improve readability.

As previously mentioned, the revisions to the Project and alternatives descriptions in the Final EIR do not change the fundamental nature or main features of the Project or alternatives. None of the comments, responses, or Final EIR revisions constitute “significant new information” that would require further Draft EIR recirculation under CEQA Guidelines Section 15088.5. Commenting agencies will receive a notice of the Final EIR’s availability, including proposed responses to their comments and proposed revisions to the EIR, at least 10 days before Project approval.

Prior to any decision on the Project, the Board will review the Final EIR and consider certifying the document and approving the Project or an alternative at a regularly scheduled Board meeting. Prior to making a decision on the Project, the Valley Water Board must certify that: (1) the Final EIR has been completed in compliance with CEQA, (2) the Final EIR was presented to the decision-making body of the lead agency (Valley Water Board), and (3) the decision-making body (Valley Water Board) reviewed and considered the information in the Final EIR prior to approving a project (CEQA Guidelines Section 15090). Following EIR certification, the Valley Water Board would then consider adopting written findings for each significant adverse environmental effect identified in the EIR (*CEQA Guidelines* Section 15091) and a statement of overriding considerations (*CEQA Guidelines* Section 15093). At the time that CEQA findings are adopted, Valley Water would also adopt a mitigation monitoring and reporting program for adopted mitigation measures. Descriptions of these documents are as follows:

- **Findings/Statement of Overriding Considerations.** For each significant impact of the Project identified in the EIR, Valley Water must find, based on substantial evidence, that either: (1) the Project has been changed to avoid or substantially reduce the magnitude of the impact, (2) changes to the Project are within another agency’s jurisdiction and such changes have or should be adopted, or (3) specific economic, social, or other considerations make the mitigation measures or Project alternatives infeasible (CEQA Guidelines Section 15091). A Statement of Overriding Considerations must be adopted for significant unavoidable impacts that sets forth the specific social, economic, or other reasons supporting the agency’s decision (CEQA Guidelines Section 15093).

- **Mitigation Monitoring Reporting Program.** CEQA requires the lead agency to adopt a Mitigation Monitoring and Reporting Program for mitigation measures that are adopted to avoid or substantially lessen significant effects on the environment. (CEQA Guidelines Section 15097[a]).

After these actions, Valley Water would consider whether to approve the Project or an alternative. If the Board decides to certify the EIR and approve the Project or an alternative, Valley Water would then file a Notice of Determination.

Chapter 1
INTRODUCTION

The Santa Clara Valley Water District (Valley Water) has prepared this ~~Draft~~ Final Environmental Impact Report (EIR) to provide the public, responsible agencies, and trustee agencies with information regarding the potential environmental effects of the Anderson Dam Seismic Retrofit Project (Project). The Project involves retrofitting and upgrading Anderson Dam and associated facilities to meet Federal Energy Regulatory Commission (FERC), California Department of Water Resources (DWR) ~~California Department of Water Resources,~~ Division of Safety of Dams (DSOD), and Valley Water public safety requirements, decommissioning the hydroelectric facility at the dam to reduce operating costs, implementing Conservation Measures that include Phase 1 measures described in the Fish and Aquatic Habitat Collaborative Effort (FAHCE) *Settlement Agreement Regarding Water Rights of the Santa Clara Valley Water District on Coyote, Guadalupe and Stevens Creeks*, initialed by the Initialing Parties on May 27, 2003 (hereafter referred to as the FAHCE *Settlement Agreement*; FAHCE 2003) and Fish Habitat Restoration Plan (FHRP) within Coyote Creek, and continuing to operate the dam after retrofit, consistent with the FAHCE rule curves. Valley Water has prepared this EIR pursuant to requirements under the California Environmental Quality Act (CEQA) (Public Resources Code [PRC] section 21000 et seq.) and the *CEQA Guidelines* (14 California Code of Regulations [CCR] section 15000 et seq.).

The revised Draft EIR—including new comment response chapters (Chapters 7 and 8) with public comments and responses, as well as technical appendices, some of which have been revised — constitutes the Final EIR for the Project, consistent with *CEQA Guidelines* requirements. The Final EIR is an informational document prepared by the lead agency that must be considered by decision makers before approving a proposed project. The CEQA Guidelines (section 15132) specify that a Final EIR shall consist of the following elements:

- Draft EIR or a revision of the draft
- Comments and recommendations received on the Draft EIR, verbatim or summarized
- List of persons, organizations, and public agencies that commented on the Draft EIR
- Responses of the lead agency to significant environmental points raised in the review and consultation process
- Any other information added by the lead agency

The Final EIR integrates the Draft EIR released on September 1, 2023, and the Partially Recirculated Draft EIR released on August 5, 2024. The following types of further revisions have been made to the Draft EIR and Partially Recirculated Draft EIR text. These are shown in underline and ~~strikeout~~ format.

- Minor revisions to the Project description, impact analyses, and alternatives to respond to Draft EIR and Partially Recirculated Draft EIR comments, and input from regulatory agencies.
- Valley Water-initiated minor changes to the Project description, impact analyses, and alternatives.
- Other minor Valley Water-initiated corrections, updates, clarifications and amplifications.

Refer to Section 1.7.7 for more details on the changes incorporated into this Final EIR. The revisions to the Project and alternatives descriptions do not change the fundamental nature or main features of the Project or alternatives, and none of the revisions to the Draft EIR or Recirculated Draft EIR made in the Final EIR constitute significant new information requiring recirculation of the EIR (CEQA Guidelines Section 15088.5).

Chapter 1 provides an overview of the Project's geographic area and gives a brief history of the Project, including evolving FERC and DSOD requirements, FERC-ordered ~~seismic~~ restrictions, and the FERC Order Compliance Project (FOCP) and FAHCE background. This chapter also defines the requirements and scope of the EIR analysis and offers clarity about how this EIR will be used in agency decision-making. Finally, Chapter 1 provides an overview of the agency coordination and public involvement processes, including opportunities for public input, ~~identifies areas of controversy and issues to be resolved,~~ and summarizes the organization of the EIR.

1.1 Geographic Area Overview

1.1.1 Coyote Creek Watershed

European settlement and the initiation of irrigated farming resulted in significant changes to natural stream conditions and hydrology of the Coyote Creek watershed. To contain flood flows, stream channels were enlarged, and levees were constructed. To quickly convey flood flows through vulnerable portions of the lower watersheds, previously natural stream channels were hardened with concrete and/or straightened. In addition, urbanization greatly reduced the amount of permeable land, resulting in faster runoff occurring in the streams.

Since the formation of Valley Water, additional changes to streams and the watershed have occurred through the construction and operation of stormwater, flood management, and water supply facilities. Modifications to the streams included the building of dams, percolation ponds, levees, canals, pipelines, ditches, culverts, concrete channels, flow modification structures, diversion structures, fish ladders, and other facilities.

1.1.2 Anderson Reservoir and Dam

Anderson Reservoir is a major water supply facility for the approximately 1.9 million people of Santa Clara County, located adjacent to Morgan Hill, California, about 18 miles southeast of San José (**Figure 2-1** in Chapter 2, *Project Description*). Anderson Reservoir is the largest of the ten reservoirs owned and operated by Valley Water and provides a greater water storage capacity than the other nine reservoirs combined. It is a critical facility to Valley Water and the communities it serves.

The Anderson Reservoir Dam was completed for water supply and groundwater recharge purposes in 1950 as a zoned, rockfill embankment dam. It has a maximum height of approximately 240 feet and impounds up to 90,373 acre-feet (AF) of water at its maximum reservoir operating elevation,[1] more than all the other reservoirs in the county combined.

Anderson Reservoir and Dam are operated and maintained under licenses granted by the DSOD and a conditional exemption from FERC, as well as water rights licenses administered by the State Water Resources Control Board (SWRCB). Valley Water holds SWRCB water rights licenses for the Coyote Creek watershed that allow water diversion and storage for irrigation and domestic uses. Corresponding facilities manage and release instream flows to creeks and rivers in the Project Area and recharge the Santa Clara Plain portion of the Santa Clara Subbasin, where released water is used to provide instream recharge for water supply, prevent groundwater pumping-related subsidence, and provide municipal and industrial supplies when diverted from the creeks to off-stream percolation facilities.

Anderson Reservoir also provides incidental flood protection to properties and property owners near Coyote Creek by capturing and storing stormwater and then releasing it at a time when the creek would normally be dry. The water released percolates into the creek bed or is rediverted from the creek into percolation ponds to support groundwater recharge. Releasing stored water into the creek also provides incidental ecological benefits, since water is present in the creek to provide cooler flows when the creek might otherwise be dry or exhibiting higher temperatures and is useful to aid migration of steelhead and other migratory fish. Additionally, Valley Water's Anderson Dam Hydroelectric Facility, located along Cochrane Road to the west of Anderson Dam, generates energy from water released from the Anderson Dam through its outlet pipe. Throughout the lifetime of the facility, it has generated approximately 39,700,000 kilowatt-hours (kWh) of renewable energy. Anderson Reservoir operations also incidentally provide reservoir and creekside recreation opportunities and a source of water for fighting fires.

Anderson Dam and Reservoir are subject to dam safety regulations and requirements established by the DSOD and FERC. These regulations include requirements to assemble a team of independent experts to inspect Anderson Dam every 5 years to evaluate all conceivable potential risks to the dam and develop strategies to minimize these risks. The Project involves retrofitting and upgrading Anderson Dam and associated facilities to meet FERC and DSOD requirements. These include DSOD requirements to modify the outlet works at Anderson Reservoir so that it is capable of drawing down the reservoir's maximum storage depth by 10 percent in 7 days and full contents in 90 days (DSOD 2018 ~~2017~~), FERC requirements that the dam embankment be capable of withstanding the maximum credible earthquakes (MCEs) on the Calaveras and Coyote Creek Faults, and FERC requirements that the spillway safely pass the flood flows related to passage of the probable maximum flood (PMF) event and emergency reservoir drawdown (~~FERC 2021a~~).

1.2 Valley Water Mission

Valley Water was created by an act of the California Legislature and operates as a California Special District with jurisdiction throughout Santa Clara County. Valley Water's mission is to

[1] Anderson Reservoir was constructed in 1950 with a maximum storage capacity of 90,373 AF. Due to sedimentation, the maximum storage available in 2020, assuming the reservoir had been operated at the maximum dam elevation, was approximately 89,278 AF (URS 2020).

provide Silicon Valley safe, clean water for a healthy life, environment, and economy. Valley Water is entrusted to serve the public by executing its mission for the benefit of the community and is accountable for executing its responsibilities safely, with honesty and integrity, and fulfilling the vision that Valley Water is nationally recognized as a leading water resources management agency.

Valley Water began managing water resources in the county in 1929, largely in response to the over pumping of Santa Clara Valley groundwater. Valley Water constructed conservation reservoirs to capture rainfall and replenish the underground aquifer through managed groundwater recharge.

Valley Water manages streams, canals, reservoirs, dams, pipelines, groundwater percolation facilities, and water treatment plants throughout the county to fulfill its responsibilities. Valley Water accomplishes its responsibilities in an environmentally responsible and cost-effective manner.

To meet countywide needs, Valley Water's water supply and distribution system relies on the following major facilities (Valley Water 2019a):

- ten surface raw water reservoirs, totaling 169,000 AF of reservoir storage capacity
- five instream water supply diversion dams
- 279 miles of natural channels and 44 miles of concrete-lined channels
- 17 miles of raw surface water canals and ditches
- 25 groundwater recharge pond facilities
- 98 miles of controlled instream recharge
- 142 miles of pipelines
- three raw water pumping stations
- three drinking water treatment plants
- one advanced water purification plant

As Santa Clara County's water wholesaler, Valley Water ensures a dependable supply of clean, safe water for homes and businesses. Valley Water currently provides approximately 284,000 acre-feet per year (AFY) of water for municipal, industrial, agricultural, and environmental uses (Valley Water 2017a). As the agency responsible for local flood protection, Valley Water also works diligently to protect Santa Clara Valley residents and businesses from the devastating effects of flooding. Valley Water's stream stewardship includes creek restoration and wildlife habitat projects, mitigation monitoring, pollution prevention efforts, and a commitment to natural flood protection.

Anderson Reservoir is part of Valley Water's raw water distribution system, and various infrastructure allows for operational flexibility of the reservoir and system. Anderson Reservoir can deliver water to the Anderson Dam Hydroelectric Facility below Anderson Dam, which then releases the water to Coyote Creek. In addition, Anderson Reservoir stores local runoff and imported water allocations from the Central Valley Project (CVP) that are conveyed to Anderson Reservoir through the Santa Clara Conduit. CVP water from San Luis Reservoir can also be released directly to Coyote Creek at the Coyote Discharge Line (CDL) turnout near the Anderson Dam Hydroelectric Facility about 1,300 feet downstream of Anderson Dam.

Due to its operational flexibility, size, and location, Anderson Reservoir has also been the Santa Clara Valley's most important source of emergency water supply. The reservoir was operated with DSOD restrictions, but prior to the FERC Order, to reserve 20,000 AF in the event of a water emergency, such as a pipeline disruption, prolonged power failure at the Pacheco Pump Plant, or severe drought (Valley Water 2019).

1.3 Project Background

1.3.1 Project Need and Purpose

As mentioned above, Anderson Dam and Reservoir are subject to dam safety regulation by the DSOD and FERC (FERC Project 5737). Anderson Dam is classified under FERC guidelines as a "High Hazard Potential" dam due to the potential incremental loss of life should failure occur.

Between 2008 and 2016, several dam safety deficiencies associated with seismic shaking, fault offset, flood capacity, and emergency drawdown capabilities were identified Anderson Dam Seismic Retrofit Project Planning Study Report (Valley Water 2017b):

- the presence of liquefiable materials in the embankment and foundation of the dam that could result in major slumping and failure of the embankment following a future large earthquake
- the presence of conditionally active[2] faults in the foundation that could rupture the existing low-level outlet
- a spillway that has inadequate capacity to safely pass large floods
- limitations in the dam outlet's capacity to quickly draw down the reservoir during floods or other emergency events

Additionally, in 2011, a Seismic Stability Evaluation (Valley Water 2011) identified potential embankment instability as a result of seismic shaking and liquefaction. The Project was initiated to remedy these seismic deficiencies and subsequently evolved as described in the next section in *Project History*.

The purpose of the Project is to seismically retrofit, maintain, and operate Anderson Dam and Reservoir to meet FERC and DSOD requirements, thereby allowing Valley Water to maximize water supply, groundwater recharge, and related incidental benefits, while avoiding and minimizing environmental impacts of the implementation of those safety directives and requirements. Specific project objectives are described in Chapter 2, *Project Description*.

---

[2] Based on DSOD fault activity criteria (Fraser 2001), ***active*** faults have experienced surface or subsurface displacement in the last 35,000 years or have geomorphic evidence of latest Pleistocene displacement; ***conditionally active*** faults have experienced surface or subsurface displacement in the last 1.6 million years and have a displacement history during the last 35,000 years that is not known with sufficient certainty to consider the fault an active or inactive seismic source, or a pre-Quaternary fault that can be reasonably shown to have attributes consistent with the current tectonic regime; and ***inactive*** faults have had no surface or subsurface displacement in the last 35,000 years, as demonstrated by a confidently located fault trace that is consistently overlain by unbroken geologic materials 35,000 years or older or by other observation indicating lack of displacement. Faults that have no suggestion of Quaternary activity are presumed to be inactive.

1.3.2 Project History

The Project was initiated in 2009. At that time, Valley Water voluntarily established a reservoir restriction of 45 feet below the crest of the existing dam (equivalent to approximately 61,000 AF of reservoir storage, or 68 percent capacity). This voluntary restriction of the reservoir was reviewed and accepted by dam safety regulators, whereby the restricted elevation level was deemed acceptable for interim earthquake protection, water supply, and environmental protection pending CEQA compliance, regulatory permitting, and detailed design processes to address retrofitting the dam. Valley Water identified project activities in coordination with resource agencies and stakeholders beginning in 2009 at the outset of the Project and engaged the public as part of the CEQA process with the release of a Notice of Preparation (NOP) and initiation of public scoping in 2013 (Section 1.7 ~~1.8~~, *Agency Coordination, ~~and~~ Public Involvement Process, and CEQA Process*).

From that time through early 2020, Valley Water prepared Project design plans under the regulatory guidance of DSOD and FERC and consulted informally with environmental regulators regarding required environmental review and permitting documents for the Project. By early 2020, construction of the Project was scheduled to start in the fall of 2022.

On February 20, 2020, FERC staff determined that, due to limited existing outlet capacity at Anderson Dam and the presence of densely populated areas downstream of the dam, Valley Water needed to take additional, immediate measures to further reduce the risk of failure from an earthquake and a maximum probable flood event as much as possible until the Project could be implemented. FERC ordered Valley Water to implement interim risk reduction measures (IRRM) in advance of the Project (FERC 2020a; FERC IRRM Order). The IRRMs required, among other things, drawdown of Anderson Reservoir and expedited construction of the Anderson Dam Tunnel Project (ADTP). FERC also directed Valley Water to secure alternative emergency water supplies and to work with FERC staff and federal, state, and local resource agencies to develop Conservation Measures to avoid and minimize environmental impacts of IRRMs.

Pursuant to the FERC IRRM Order, Valley Water implemented IRRMs, including: (1) maintaining the reservoir no higher than elevation (elev.) 565 feet effective immediately in 2020; (2) lowering Anderson Reservoir to approximately elev. 490 feet (deadpool[3]) beginning no later than October 1, 2020; (3) taking all appropriate measures to maintain and quickly lower the reservoir to deadpool in the event of significant inflow once the approximately elev. 490 feet was reached; (4) assessing and addressing the issue of potential reservoir rim instability during drawdown; (5) expediting design, construction, and operations of the ADTP; (6) working with applicable regulatory agencies and others to avoid and minimize adverse effects of the IRRMs on groundwater recharge, water supply, and the environment; and (7) advancing the Project engineering and environmental review with haste. Conservation Measures developed by Valley Water in coordination with regulatory agencies included fish rescue and fish and habitat monitoring; dam outlet channel modifications to stabilize and improve fisheries habitat conditions; reservoir bank and rim stabilization work; construction and construction period operation of the reservoir, ADTP, Cross Valley Pipeline Extension, CDL, and Coyote Creek Chillers to provide water supply, recharge, and incidentally, creek environmental flows; Phase 1 Coyote

[3] Deadpool is the point at which flows through the Anderson outlet structure cease and is represented by the existing invert elevation (approximately elev. 490 feet) of the deepest intake port to the outlet of Anderson Reservoir.

Percolation Dam modifications to make operations more flexible and improve fish passage; Coyote Creek flood management projects to reduce potential for flooding impact of construction period operations of the Anderson Dam Tunnel and existing outlet; and habitat restoration.

In response to the FERC IRRM Order, Valley Water developed the FOCP, described in Section 1.3.3, to implement all FERC-directed IRRMs, and to identify and implement avoidance and minimization measures (AMM) necessary to address anticipated adverse environmental effects of complying with the FERC IRRM Order. Valley Water also requested FERC to initiate emergency consultation processes with regulatory agencies regarding the FERC IRRM Order, as appropriate. Technical Recommendations and recommended conditions of other regulatory agencies were incorporated into two additional FERC orders (FERC 2020b, 2021~~a~~) for the FOCP (described below in Section 1.3.3). FERC-ordered actions and regulatory agency Technical Recommendations resulted in subsequent changes to the Project's design plans, environmental and permitting documents, and construction schedule.

Between February of 2020 and the time this EIR was prepared, Valley Water has prepared new, updated design plans for the Project. With respect to operations, Valley Water proposes to implement the reservoir release rule curves (developed pursuant to the FAHCE *Settlement Agreement* by the FAHCE Technical Advisory Committee, which included representatives from all regulatory agencies. Proposed operations pursuant to the FAHCE rule curves are described below in Section 1.3.4.) ~~As discussed later in Chapter 2, *Project Description*, c~~ Construction of the Project is currently proposed to start in 2027 ~~early 2026~~.

1.3.3 FERC Order Compliance Project

In response to the FERC IRRM Order, Valley Water filed a Final Reservoir Operations and Drawdown Plan (Valley Water 2019) on July 27, 2020, to describe how Valley Water planned to implement the IRRMs related to drawdown and limiting storage in the reservoir until completion of construction of the Project Seismic Retrofit improvements, as well as describing the Conservation Measures proposed to address those actions.[4] The IRRMs specified in the FERC directive, together with the Conservation Measures that FERC directed Valley Water to develop to avoid and minimize adverse environmental impacts of those IRRMs, are described in the Final Reservoir Operations and Drawdown Plan and are collectively referred to as the FOCP.

On October 1, 2020, as Valley Water was initiating the reservoir drawdown, FERC issued its Order Approving, In Part, Reservoir Drawdown and Operations Plan, and an Environmental Assessment for Dam Safety Interim Risk Reduction Measures and Reservoir Drawdown and Operations regarding portions of the Reservoir Operations and Drawdown Plan (FERC 2020b). Later, on February 2, 2021, FERC issued its second Order Approving, In Part, Reservoir Drawdown and Operations Plan, and a Supplemental Environmental Assessment for Dam Safety Interim Risk Reduction Measures and Reservoir Drawdown and Operations regarding portions of the Reservoir Operations and Drawdown Plan, including construction of the ADTP and implementation of related Conservation Measures not addressed in the October 1, 2020, order (FERC 2021~~a~~). Both FERC orders require Valley Water to implement certain U.S. Fish and Wildlife

[4] The Final Reservoir Operations and Drawdown Plan (Valley Water 2019) was developed through the Fisheries Technical Working Group (TWG) that includes Valley Water, NMFS, and CDFW.

Service (USFWS), National Marine Fisheries Service (NMFS), and California Department of Fish and Wildlife (CDFW) Technical Recommendations to address environmental impacts of the FOCP, as well as measures recommended by other state and federal regulatory agencies, as modified by FERC staff. All the recommended aquatic Technical Recommendations were incorporated into the FOCP pursuant to FERC 2020b and FERC 2021~~a~~.

The FOCP, a related but independent project from the Project, is presently underway and projected to be completed in 2026 ~~summer 2025~~; it consists of the following main Project components (Valley Water 2020b):

- *Reservoir Drawdown to Deadpool.* Safe drawdown of Anderson Reservoir to deadpool and reservoir operation and water level maintenance until Anderson Dam tunnel is operational.
- *Anderson Dam Tunnel Construction.* Construction of a new outlet system that includes a new low-level outlet tunnel, lake tap, outlet structure, discharge channel (South Channel) improvements, and reopening of the original Coyote Creek channel (North Channel) downstream of the existing dam, and outlet weirs to govern releases to the channels. The new outlet system will be constructed at the base of Anderson Dam, through the right (looking downstream) abutment, along the southern side.
- *Anderson Dam Tunnel Operation and Maintenance.* Operation of Anderson Dam tunnel and water management procedures are anticipated to occur until seismic deficiencies can be fully mitigated at Anderson Dam (i.e., completion of Project).
- *Avoidance and Minimization Measures.* Implementation of measures to secure alternative water supplies and minimize environmental effects, including:
    - *Bank and Rim Stability Improvements*. Geotechnical investigations and installation of monitoring devices for areas of known landslides along Anderson Reservoir rim to address potential impacts of reservoir drawdown. Installation of additional structural improvements to protect against potential landslides will be installed, as required.
    - *Existing Intake Structure Modifications*. Geotechnical investigations and installation of monitoring devices near the intake structure to address potential geotechnical impacts of dewatering on the existing outlet structure. Installation of additional structural improvements to reinforce the existing Anderson Dam intake structure will be installed, as required.
    - *Creek Channel and Bank Erosion Control Modifications.* Modifications required to minimize erosion to accommodate drawdown and water management operations downstream of Anderson Dam, including reestablishment of the North Channel and stabilization with habitat measures in both the North and South Channels, to create two outlet channels and reduce the potential for erosion from outflows through the existing outlet and Anderson Dam Tunnel when completed.
    - *Imported Water Releases and Cross Valley Pipeline Extension.* Provide for imported water releases to Coyote Creek through the existing CDL immediately downstream of Anderson Dam and construction of a new Cross Valley Pipeline spur to discharge downstream of the County of Santa Clara-owned Ogier Ponds. Water releases from these pipelines will support water supply maintenance, groundwater recharge, subsidence prevention, and incidental in-stream environmental flows when

Anderson Reservoir is unavailable to provide water supply, storage, and releases needed.

- *Phase 1 Coyote Percolation Dam Project*. Replacement of the existing flashboard dam with an inflatable bladder dam that can quickly be deployed when inflows are low and deflated to allow higher flows to pass safely, improving flexibility in flow operations and fish passage during the FOCP. The inflatable bladder dam will protect aquatic resources, water supply, groundwater recharge, and reduce subsidence from the effects of dewatering and maintaining a lower elevation in the reservoir.
- *Coyote Creek Flood Management Measures*. Acquisition or elevation of ten residential properties and construction of six spans of off-stream floodwalls or levee. These measures will reduce flood risks from higher Coyote Creek flows during major storm events (i.e., a 10-year storm event) caused by maximum Anderson Dam tunnel flows combined with outflows from the existing outlet and local tributary inflows.
- *Coyote Creek Habitat Restoration Measures.* To provide compensatory mitigation for unavoidable temporary and permanent FOCP impacts to waters, wetlands, and riparian habitats, habitat restoration measures include aquatic and riparian habitat re-establishment and enhancement at construction areas; aquatic, wetland, and riparian habitat creation at the Coyote Creek North Channel; creek and riparian habitat enhancement along Coyote Creek South Channel; and creek creation and enhancement in Coyote Creek below the William F. James Boys Ranch.
- *Implementation of Additional FOCP-Specific Avoidance and Minimization Measures.* Implementation of Project-specific best management practices (BMP), Coyote Creek AMMs, and other environmental protection measures identified for the FOCP. Such measures include habitat, sediment, water quality, and fish monitoring and fish rescue efforts, when needed.

1.3.4 Fish and Aquatic Habitat Collaborative Effort

FAHCE is an existing, long-term program that Valley Water has agreed to implement in coordination with NMFS, CDFW, USFWS, and several nongovernmental environmental organizations. FAHCE seeks to improve aquatic spawning and rearing habitat and fish passage for migration to and from the watersheds of the Coyote and Stevens Creeks and Guadalupe River.

The program arose from the proposed settlement of a water rights complaint. In 1996, the Guadalupe-Coyote Resource Conservation District (GCRCD) filed a complaint with the SWRCB. The complaint alleged that Valley Water operations affected fish and wildlife, in conflict with requirements of the Water Code, Fish and Game Code, and other California laws.

In response to the 1996 complaint, Valley Water convened local environmental organizations and state and federal resource agencies in settlement negotiations and developed what is known as the FAHCE. FAHCE participants currently include Valley Water, Trout Unlimited, California Trout Inc., the Pacific Coast Federation of Fishermen’s Associations, NMFS, USFWS, and CDFW, collectively referred to as the “Initialing Parties.” Measures developed through

FAHCE are intended to modify instream flows and improve habitat conditions, as appropriate, to meet the management objectives specified in the FAHCE *Settlement Agreement*.

The FAHCE *Settlement Agreement* contains a restoration program that details those provisions defined during the FAHCE process for flow measures, fish habitat restoration, and barrier remediation measures in three watersheds: Coyote Creek, Stevens Creek, and Guadalupe River. The FAHCE Technical Advisory Committee (which included Valley Water staff, technical consultants, and representatives of the Initialing Parties) determined that implementation of these measures would help restore and maintain healthy populations of Central California Coastal steelhead trout (*Oncorhynchus mykiss*; steelhead trout or steelhead) and Central Valley fall-run Chinook salmon (*Oncorhynchus tshawytscha*; Chinook salmon or Chinook) by providing: (1) suitable spawning and rearing habitat within each watershed, and (2) adequate passage for adult steelhead trout and salmon to reach suitable spawning and rearing habitat and for outmigration of juveniles.

Valley Water has prepared a FHRP to comprehensively implement the FAHCE *Settlement Agreement* (see Appendix A of the FAHCE Final EIR (Valley Water 2023) ~~B for portions of the FHRP applicable to Coyote Creek~~), including the creek management objectives and all measures approved by the Technical Advisory Committee for Coyote Creek. It includes Phase 1 measures to be implemented during the first 10 years and an Adaptive Management Program (AMP) that would monitor Phase 1 measures and determine whether additional Phase 2 or Phase 3 measures (currently undefined) are needed to achieve management objectives. Phase 4 is a perpetual management phase that could directly follow Phase 1, 2, or 3, depending on when the management objectives are found to be met. The FHRP was intended to serve as the basis for settlement between the complainants and Valley Water, if accepted by all parties and approved by the SWRCB.[5] The FHRP addresses all components of the FAHCE *Settlement Agreement,* including the long-term adaptive management of Coyote Creek measures and provides additional detail about how each Phase 1 measure has been or would be implemented. Monitoring and maintenance of measures completed, or of certain existing Valley Water facilities, are also included.

In 2015, Valley Water published an NOP for a single EIR that would analyze impacts of FAHCE *Settlement Agreement* implementation in all three watersheds (i.e., Coyote Creek, Stevens Creek, and Guadalupe River), and Valley Water began preparation of a draft FHRP and Draft EIR that covered all three watersheds.

In 2019, however, Valley Water decided it would be more appropriate and efficient to move CEQA review of the Coyote Creek watershed Phase 1 FAHCE measures to the Project EIR. This was decided primarily because the Project post-construction reservoir operations would be based on the Anderson Reservoir FAHCE rule curves (i.e., measures governing operational flow), and because the Project Conservation Measures would include Coyote Creek Phase 1 nonflow measures (e.g., geomorphic and habitat restoration, barrier remediation, development of environmental resource enhancement or monitoring plans, and/or implementation of practices intended to modify instream flows and improve habitat conditions).

[5] Valley Water subsequently found out the SWRCB considers the complaint "closed." However, Valley Water still intends to amend its water rights consistent with the FAHCE *Settlement Agreement*.

Therefore, Valley Water's CEQA review of the FAHCE *Settlement Agreement* measures occurs in two EIRs: the FAHCE Program EIR for Stevens Creek and Guadalupe River (Valley Water 2023) and the Project EIR for Coyote Creek. This approach is consistent with CEQA requirements to avoid "piecemealing" because (1) the Coyote Creek watershed is physically separated and isolated from the Stevens Creek and Guadalupe River watersheds and (2) the Coyote Creek, Stevens Creek, and Guadalupe River FAHCE measures have independent utility in that Conservation Measures within Coyote Creek could be implemented even if the Stevens Creek and Guadalupe River measures were not and vice versa. All things considered, for ease of future FAHCE implementation, Valley Water has decided to retain a single FHRP and AMP that includes a common AMP for all three watersheds.

The EIR, therefore, evaluates the impacts of the FAHCE Coyote Creek Phase 1 flow and nonflow measures (included in this EIR as Project components) and evaluates related monitoring, maintenance, and potential adaptive actions related to those measures. FAHCE Phase 2 and 3 measures, if determined to be necessary to meet FAHCE *Settlement Agreement* management objectives, may require additional CEQA review prior to implementation. The Project EIR does not evaluate the impacts of potential FAHCE Phase 2 and Phase 3 additional measures, because these measures are not currently known, nor are they reasonably foreseeable. Phase 4 is a perpetual management phase that could directly follow Phase 1, 2, or 3, depending on when the management objectives are found to be met. Phase 4 would include monitoring Valley Water facilities and the continuation of the AMP. Phase 4 measures following Phases 1, 2 or 3 may also require additional CEQA environmental review prior to implementation.

Table 1-1 provides a summary of the FAHCE *Settlement Agreement* terminology used throughout this EIR.

Table 1-1. Fish and Aquatic Habitat Collaborative Effort Program Terminology

Term (Acronym)	Definition
Fish and Aquatic Habitat Collaborative Effort (FAHCE)	The collaboration that began in 1996 between Valley Water, federal and state resource agencies, and Initialing Parties to identify actions to balance Valley Water's water supply operations with aquatic habitat needs in the Stevens Creek, Guadalupe River and Coyote Creek watersheds—these are reflected in the FAHCE *Settlement Agreement*.
Fish Habitat Restoration Plan (FHRP)	A Valley Water plan prepared to implement the FAHCE *Settlement Agreement*. It includes "Phase 1" measures to be implemented during the first 10 years and an AMP that would monitor Phase 1 measures and determine whether additional "Phase 2" or "Phase 3" measures (currently undefined) are needed to achieve management objectives. Phase 4 is a perpetual management phase that could directly follow Phases 1, 2, or 3, depending on when the management objectives are found to be met.
FAHCE Program Environmental Impact Report (EIR)	An EIR prepared for the disclosure of impacts related to implementation of the FAHCE FHRP Phase 1 measures in the Stevens Creek and Guadalupe River watersheds, amendments to associated Valley Water water rights (within those two watersheds), and implementation of the FHRP AMP (within those two watersheds).

Key: AMP = Adaptive Management Program; EIR = Environmental Impact Report; FAHCE = Fish and Aquatic Habitat Collaborative Effort; FHRP = Fish Habitat Restoration Plan

1.3.5 Coyote Creek Water Rights

Valley Water holds ~~five~~ four water right licenses and one permit for water diversions in the Coyote Creek watershed; each license allows diversions for irrigation and domestic uses, currently identified as the "beneficial uses" for these Valley Water facilities.

Pursuant to the FAHCE *Settlement Agreement*, Valley Water is proposing changes to all its currently held water rights in the Project area as part of the Project. The proposed water rights changes are ~~were~~ intended to resolve an SWRCB water rights complaint[6] and would incorporate Valley Water's implementation of the Coyote Creek-related measures specified in the FAHCE *Settlement Agreement* and included in the FHRP. Valley Water's draft water rights petitions are concurrently being reviewed by the SWRCB. **Table 1-2** summarizes the existing and proposed purpose of use for each of Valley Water's Coyote Creek water rights.

Table 1-2. Summary of Proposed Coyote Creek Water Rights Amendments

Valley Water Facility and License Number	Water Body	Existing Purpose of Use	Proposed Purpose of Use
Coyote Reservoir 7211	Coyote Creek	Domestic, irrigation, minor industrial, incidental recreation	Municipal, minor industrial, fish and wildlife preservation and enhancement
Coyote Percolation Pond 2210	Coyote Creek	Domestic and irrigation	Municipal, fish and wildlife preservation and enhancement
Anderson Reservoir 7212	Coyote Creek	Domestic, irrigation, industrial, recreational, incidental power	Municipal, industrial, incidental power, fish and wildlife preservation and enhancement
Anderson Reservoir 10607	Coyote Creek	Domestic, industrial, recreational, incidental power	Municipal, industrial, incidental power, fish and wildlife preservation and enhancement

Because approving the amendments is a discretionary action, the SWRCB, as a responsible agency, would rely on this EIR for CEQA compliance before approving the water rights amendments. The Project EIR would provide CEQA compliance for SWCRB's approval of Valley Water's water rights Petitions for Change in the Coyote Creek watershed.

[6] Valley Water subsequently discovered that the SWRCB considers the complaint "closed." However, Valley Water still intends to amend its water rights consistent with the FAHCE *Settlement Agreement*.

1.4 Overview of California Environmental Quality Act Requirements

CEQA is the cornerstone of environmental law and policy in California. CEQA's primary objectives (*CEQA Guidelines* section 15002) are to:

- ensure that the significant environmental effects of proposed activities are disclosed to decision-makers and the public
- identify ways to avoid or reduce environmental damage; prevent environmental damage by requiring implementation of feasible alternatives; and avoid, minimize, reduce, and/or compensate for environmental impacts through implementation of mitigation measures
- disclose the reasons for agency approval of projects with significant environmental effects
- foster multidisciplinary interagency coordination in the review of projects
- allow for public participation in the planning process

With certain limited exceptions, CEQA requires all state and local government agencies to consider the environmental impacts of projects over which they have discretionary authority before taking action on those projects. It establishes both procedural and substantive requirements that agencies must satisfy to meet CEQA's objectives. For example, if the CEQA lead agency determines that a proposed project could result in significant environmental impacts, CEQA requires that the agency prepare an EIR analyzing both the proposed project and a reasonable range of feasible alternatives.

As described in section 15121(a) of the *CEQA Guidelines*, an EIR is a public information document that assesses potential environmental effects of a proposed project and identifies mitigation measures and alternatives to the project that could reduce or avoid adverse environmental impacts. Other key procedural requirements include developing a plan for mitigation measure reporting and monitoring and accomplishing specific noticing and distribution steps to facilitate public involvement in the environmental review process.

The EIR is an informational document used in the planning and decision-making process. It is not the purpose of an EIR to recommend either approval or denial of a project.

Valley Water is the lead agency under CEQA because it is the public agency proposing to approve and execute the Project. The DSOD, SWRCB, CDFW, Santa Clara County, and Bay Area Air Quality Management District are considered responsible agencies under CEQA because they have discretionary approval over some aspect of the Project and would use this EIR for their CEQA compliance (Section 2.12, *Permits, Approvals, and Consultations* ~~2.10, *Permits and Approvals*~~).

1.5 Scope and Intent of this Environmental Impact Report

This EIR has been prepared in accordance with CEQA. The Valley Water Board of Directors will use the analyses presented in this EIR, and comments provided during the public review periods for the EIR, to evaluate the Project's environmental impacts and to consider approval of the Project.

The intent of this EIR is to evaluate in detail all the actions proposed to take place under the Project. The analysis in the EIR has been prepared at a "project level" pursuant to *CEQA Guidelines* Section 15161. Accordingly, this EIR focuses on changes in the environment that could result during all phases of the Project, including planning, construction, operation, and maintenance.

1.6 Selected Other Related Valley Water Projects and Programs (Not within Scope of this Document)

Valley Water is undertaking several other projects or programs, located within or nearby the Coyote Creek watershed that are not part of the Project but may affect related resources or have similar objectives but independent utility. These are noted in Chapter 3 of this EIR when relevant to the impact analysis and will be addressed, as appropriate, in the analysis of cumulative effects ~~in~~ throughout Chapter 3 ~~4~~. These related projects and programs are listed in **Table 1-3**. Selected Other Valley Water Projects and Programs with a more detailed description and analysis of selected projects and programs are included in the *Cumulative Impacts* sections throughout Chapter 3 of this EIR ~~in Section 4.5, *Cumulative Impacts*~~.

Table 1-3. Selected Other Valley Water Projects and Programs

Valley Water Project or Program	Brief Description	Relationship to the Project
FERC Order Compliance Project (Section 1.3.3)	This project implements the FERC IRRM Order in advance of the Project. IRRMs included lowering and maintaining Anderson Reservoir to approximately elev. 490 feet (deadpool); assessing and addressing potential rim instability during drawdown; implementing other Conservation Measures that are included in the FERC Order Compliance Project Habitat Mitigation and Monitoring Plan, such as the wetland bench, North Channel Improvements, and Live Oak Picnic Area Enhancement; and expediting design, construction, and operations of a new, low-level outlet.	As ordered by FERC, this project ~~Project~~ is being implemented on an emergency basis to provide immediate reduction of risk related to seismic deficiencies at Anderson Dam. This project will be implemented in advance of the Project.
FAHCE Program for Stevens Creek and Guadalupe River Watersheds (Section 1.3.4)	This project proposes implementation of the FAHCE FHRP Phase 1 measures and FHRP Adaptive Management Program in the Stevens Creek and Guadalupe River watersheds, and amendments to associated Valley Water water rights (within those two watersheds only).	The FHRP includes a common monitoring and adaptive management framework for all three watersheds (i.e., Stevens Creek, Guadalupe River, and Coyote Creek).

Valley Water Project or Program	Brief Description	Relationship to the Project
Dam Maintenance Program	The program identifies dam maintenance and repair activities to be executed in a series of 5-year work plans. The work includes regulatory compliance, for example, complying with permits issued by CDFW and the San Francisco and Central Coast RWQCBs, and a take authorization for protected terrestrial species under the <u>Santa Clara</u> Valley Habitat Plan.	Under this program, Valley Water maintains dam structures and facilities to ensure functions and operation that would be necessary to implement the Project.
Singleton Road Interim Bridge Project	The Singleton Road Interim Bridge Project removed a low-water crossing at Coyote Creek that was formerly a fish passage barrier and constructed a pedestrian bridge. Construction of the Singleton Road Interim Bridge Project was completed in December 2021.	Singleton Road Interim Bridge Project is an early implementation of the Phase 1 nonflows measures. This project removed a fish passage barrier along Coyote Creek, downstream of study area.
Stream Maintenance Program	The Stream Maintenance Program performs sediment removal, bank protection, vegetation management, and other routine maintenance activities throughout the county, including Coyote Creek. Although the primary work season is from June 15 through October 15, some stream maintenance activities can occur year-round in reaches where Valley Water holds fee title or easement.	Stream Maintenance Program work is conducted routinely in streams where the Project would be implemented.
Safe, Clean Water and Natural Flood Protection Program	The Safe, Clean Water and Natural Flood Protection Program provides grant and partnership funds for many water quality and habitat improvements projects. For example, as part of this program, Valley Water, Priority D projects are focused on restoring and protecting wildlife habitat. Work under this priority includes controlling nonnative, invasive plants, replanting natives species, and maintaining previously replated areas. Other projects include removing barriers to fish movement, improving steelhead habitat and stabilizing eroded creek banks. These priority projects also include Valley Water partially funding a creek/lake separation project in partnership with local agencies.	The <u>Project</u> ~~project~~ includes habitat restoration and removal of specific fish passage barriers to be remediated and efforts to continue removing barriers not specifically identified. As part of the <u>Project</u> ~~project~~, the Ogier Ponds Project construction is funded by more sources than just the Safe, Clean Water Program, which helps reduce the financial impact on the Safe, Clean Water Fund.

Valley Water Project or Program	Brief Description	Relationship to the Project
Mid-Coyote Creek Flood Protection Project	The Mid-Coyote Creek Flood Protection Project would construct improvements along approximately 9 miles of Coyote Creek, between Montague Expressway and Tully Road in San José.	The Mid-Coyote Creek Flood Protection Project is located downstream of the Project. The purpose of this project is to provide a 5% (20-year event) flood capacity in Coyote Creek throughout the study area.

Key: AMP = Adaptive Management Program; CDFW = California Department of Fish and Wildlife; FAHCE = Fish and Aquatic Habitat Collaborative Effort; FERC = Federal Energy Regulatory Commission; FHRP = Fish Habitat Restoration Plan; IRRM = Interim Risk Reduction Measure; Project = Anderson Dam Seismic Retrofit Project; RWQCB = Regional Water Quality Control Board

1.7 Agency Coordination, ~~and~~ Public Involvement, and CEQA Process

1.7.1 Agency Coordination

Valley Water has coordinated with a number of agencies throughout the planning process for the Project. A summary of key communications held between Valley Water and various agencies include:

- Valley Water staff have hosted regular interagency meetings since 2018, both in-person and by conference call, to discuss the Project. Interagency meetings typically have been attended by one or more individuals from the following agencies with regulatory jurisdiction over the Project: FERC Division of Hydropower Administration and Compliance (FERC DHAC), FERC Division of Dam Safety and Inspections (FERC D2SI), USFWS, NMFS, CDFW, U.S. Army Corps of Engineers (USACE), SWRCB, Regional Water Quality Control Board (RWQCB), U.S. Environmental Protection Agency (USEPA), Santa Clara Valley Habitat Agency (SCVHA), State Historic Preservation Office (SHPO), and Santa Clara County Parks and Recreation. These meetings have been held at least quarterly from 2018 to present and will continue throughout the Project.
- Valley Water organized site visits for the Project that were attended by multiple individuals representing various agencies.
- Valley Water staff and NMFS staff have participated in Fish and Frog Technical Working Group (Fish/Frog TWG) meetings with USFWS and CDFW biologists to discuss issues related to fish Conservation Measures and potential effects of those measures on other species, such as listed species like the California red-legged frog and the foothill yellow-legged frog regulated by USFWS and CDFW.
- Valley Water, NMFS, CDFW, and FERC staff formed a monthly TWG in late 2019 to discuss technical issues related to permitting biological impacts of the Project. These meetings have been held on a monthly basis since December 2019 to the present and will continue throughout the Project. Participation at the TWG meetings expanded in late 2020 to include additional resource agency staff from USFWS, SWRCB, and RWQCB. In 2021, TWG participation expanded further to also include USACE and USEPA.
- Additionally, TWG subcommittees have formed for discussion of the design of the North and South Channels, and for discussion of design and operation of the Coyote

Percolation Facility. These sub-TWG meetings are attended by Valley Water, CDFW and NMFS staff and have been held periodically as work products are available from May 2020 to present. These meetings will continue throughout the planning and design of the Project.

- Valley Water and regulatory agency executive management formed an Executive Fisheries TWG (E-TWG) with both CDFW and NMFS management. The focus of these meetings is to keep executive staff from the three agencies apprised of developments in the permitting of biological impacts for the Project. E-TWG meetings ensure timely resolution of pending issues. E-TWG meetings have occurred quarterly from March 2020 to the present and will continue throughout the Project.
- Executive management for Valley Water and state regulatory agencies (CDFW, SWRCB, RWQCB, and the Natural Resources Agency) formed an Executive Working Group (EWG). The focus of these meetings is to keep executive staff from all state regulatory agencies apprised of developments in permitting of the Project. These meetings have occurred quarterly from Spring 2021 to the present.

Quarterly updates regarding Project schedule, status, and progress were convened by Congresswoman Lofgren with Congresswoman Eshoo, Congressman Panetta, Congressman Khanna, and other state and local officials to coordinate with executive federal agency staff, including NMFS, USFWS, FERC, USACE, and Valley Water. These meetings have occurred quarterly from December 2019 to the present.

1.7.2 Public and Interest Group Engagement Process

Valley Water has conducted a total of 16 public information meetings since 2017 outside of the formal CEQA scoping process. In additional to those meetings, Valley Water has conducted the following meetings:

- 29 ~~26~~ public meetings
- 116 ~~24~~ meetings with Santa Clara County Parks
- 443 ~~370~~ meetings with regulatory agencies
- 6 ~~2~~ meetings with Tribal representatives

The Stakeholder Engagement record is provided in Appendix C.

1.7.3 California Environmental Quality Act Scoping Process

"Scoping" refers to the public outreach process used under CEQA to determine the scope and content of an EIR. The scoping comment period offers an important opportunity for public review and comment in the early phases of a project.

1.7.3.1 Notice of Preparation and Scoping Comments

The scoping process for an EIR begins with publication of the NOP as required by CEQA. The NOP provides formal notice to the public and to interested agencies and organizations that a Draft EIR is being prepared. During the scoping period, agencies and the public are invited to offer comments on the approach to environmental analysis and identify any issues of concern.

In accordance with *CEQA Guidelines* Section 15082(a), Valley Water circulated an NOP for the Project on August 13, 2013. The NOP was circulated to the public; the Governor's Office of Planning and Research State Clearinghouse; responsible, trustee, and other relevant local, state, and federal agencies; and other interested parties.

Although not specifically required by CEQA, Valley Water held an informational public scoping meeting on August 26, 2013, in the Hiram Morgan Hill Room of the Morgan Hill Community and Cultural Center, located at 17000 Monterey Road, Morgan Hill. To solicit attendance, Valley Water published advertisements in a local newspaper and mailed notices to interested parties who had signed up to receive Project-related information at previous public meetings conducted during the Project's planning phase. A scoping report, which includes the NOP and comments received in response to the NOP and at the scoping meeting, is included in this ~~Draft~~ Final EIR as Appendix B, *Notice of Preparation/Initial Study and Scoping Report*. Valley Water considered Scoping Report comments when preparing the relevant sections of this EIR.

Valley Water also prepared an Initial Study (IS) for the Project and circulated the IS for public review along with the NOP. The IS evaluated potential environmental impacts associated with the Project based on preliminary information. Valley Water determined in the IS that several environmental resource topics did not have the potential for significant impacts. For this reason, those environmental resource topics have been dismissed from further evaluation in this EIR. Determinations to dismiss any environmental resource topics from evaluation in this EIR are explained in detail as part of Section 3.0, *Regulatory and Environmental Setting and Impact Analysis*.

1.7.4 Tribal Consultation

Assembly Bill (AB) 52, passed in 2014, requires formal consultation with Native American Tribes during the CEQA process for projects that have an NOP filed on or after July 1, 2015. Formal consultation under AB 52 is not required for this EIR because the NOP was filed on August 13, 2013; however, Valley Water has provided notification letters to Tribal representatives throughout the EIR development, and has consulted with Tribes that may be affected by the Project, consistent with CEQA requirements.

1.7.5 Draft Environmental Impact Report Comments ~~Period~~

On September 1, 2023, Valley Water ~~has~~ issued a Notice of Availability of the Draft EIR to provide agencies and the public with formal notification that the Draft EIR ~~is~~ was available for review and comment. The Notice of Availability, Draft EIR and selected appendices ~~are~~ were made available at the following website: www.valleywater.org/ADSRP. The Draft EIR and all appendices ~~are~~ were also made available for review at the following locations:

Santa Clara Valley Water District
5750 Almaden Expressway
San José, CA 95118-3686
(408) 630-3055

City of Morgan Hill
17575 Peak Avenue
Morgan Hill, CA 95037

City of Morgan Hill Library
60 West Main Ave
Morgan Hill, CA 95037

~~The Draft EIR can be reviewed on any Valley Water business day between the hours of 7:30 a.m. and 5:00 p.m., Monday through Thursday, at the Valley Water headquarters building, located at 5750 Almaden Expressway, San José, CA 95118. Please contact Ms. Tiffany Chao at (408) 630-3107 to arrange a date and time for review.~~

Valley Water circulated the ~~is circulating this~~ Draft EIR for a 68-day ~~60-day~~ public review and comment period between September 1 and November 8, 2023. ~~and will host a public meeting during this period, to be announced in the Notice of Availability and on the Project website.~~ The public meeting for the Draft EIR was held on October 4, 2023, from 6:30 p.m. to 8:00 p.m. at the Morgan Hill Community and Cultural Center. The purpose of public circulation was ~~is~~ to provide agencies, stakeholders, and interested individuals with opportunities to comment on the contents of the Draft EIR.

~~Written comments concerning this Draft EIR should be mailed or emailed during this review period and should be directed to the name and address listed below. Please submit your written comments at the earliest possible date, but no later than 60 days from September 1, 2023, release of the Draft EIR on November 1, 2023. Public meeting for the Draft EIR is scheduled for October 4, 2023, from 6:30 p.m. to 8:00 p.m. at the Morgan Hill Community and Cultural Center.~~

~~Tiffany Chao, Senior Environmental Planner~~
~~Santa Clara Valley Water District~~
~~5750 Almaden Expressway~~
~~San José, CA 95118-3686~~
~~(408) 630-3107~~
~~ADSRPcomments@valleywater.org~~

~~Written comments received in response to the Draft EIR will be addressed in the Final EIR.~~

Valley Water received a total of 90 comment letters or other written communications, such as emails on the Draft EIR, before the close of the public review period. Written comments received on the Draft EIR are included and responded to in Chapter 7 of this Final EIR. Additionally, 34 letters related to Draft EIR contents were received related to the separate FERC petition process associated with the Project during the Draft EIR public review and comment period. These 34 FERC-related letters are included and addressed in Chapter 7 although they were not submitted as Draft EIR comment letters and therefore no responses were required under CEQA.

1.7.6 Partially Recirculated Draft EIR Public Comment Period

After circulation of the Draft EIR, Valley Water met with the Project Board of Consultants (BOC), which reviews the Project and makes recommendations to FERC, to discuss updated design plans and construction sequencing. In response to that meeting and BOC recommendations, Valley Water made certain construction changes such as extending work hours, adding some weekend days, and beginning work on certain Project components sooner. These proposed changes would allow Valley Water to construct planned Project components within the planned construction timeline before the wet season each year to improve its ability to complete the Project on schedule.

These Project changes necessitated revisions to certain impact analyses in the aesthetics, air quality, greenhouse gas emissions, and noise and vibration sections of the Draft EIR, as well as associated technical appendices, which were included in a Partially Recirculated Draft EIR.

On August 5, 2024, Valley Water issued a Notice of Availability of the Partially Recirculated Draft EIR to provide agencies and the public with formal notification that the Partially Recirculated Draft EIR was available for review and comment. The Notice of Availability, Partially Recirculated Draft EIR, and selected appendices were made available at the following website: https://www.valleywater.org/public-review-documents. Copies of the Partially Recirculated Draft EIR and appendices were also available for review at the following locations:

Santa Clara Valley Water District
5750 Almaden Expressway
San José, CA 95118-3686

City of Morgan Hill
17575 Peak Avenue
Morgan Hill, CA 95037

City of Morgan Hill Library
60 West Main Ave
Morgan Hill, CA 95037

Valley Water circulated the Partially Recirculated Draft EIR for a 45-day public review and comment period between August 5 and September 20, 2024.

Valley Water received a total of 11 comment letters or other written communications such as emails on the Partially Recirculated Draft EIR before the close of the public review period, Written comments received on the Partially Recirculated Draft EIR during the public review period are included and responded to in Chapter 8 of this Final EIR.

1.7.7 Preparation of Final Environmental Impact Report and Project Approval Process

The Final EIR consists of a comprehensive revision to the EIR that occurred after public circulation of the Draft EIR and Partially Recirculated Draft EIR (including technical appendices), public comments on the Draft EIR and Partially Recirculated Draft EIR received during public review periods, and responses to the public comments. Revisions include the following:

- Updates to the Project description to replace construction of the North Channel Extension with the Maintenance of the North Channel Reach
- Changes to the Ogier Ponds Conservation Measure
- Refinements to the Sediment Augmentation Program,
- Refinements to the number of construction and haul trips
- Changes to the temporary trail closures
- Changes to the construction sequencing of the Phase 2 Coyote Percolation Dam CM,

- Clarifications of the construction phase monitoring
- Other minor changes and corrections.

Changes to the Project description are reflected in revised modeling for air quality, greenhouse gasses, energy, and noise and vibration. In addition, minor changes and clarifications were made to the FAHCE-Plus Modified Alternative description and impact analysis.

Some of the Chapter 3 impact analyses and mitigation measures were revised to reflect changes in the Project description to address public and regulatory agency Draft EIR comments, and to increase accuracy, but impact significance conclusions remained the same. Preparation of a Water Quality Monitoring and Protection Plan was added as new Mitigation Measure WQ-1 to reduce significant unavoidable water quality and erosion impacts related to in-reservoir construction that were identified in the Draft EIR. Mitigation Measure REC-1 was refined based on Draft EIR comments and coordination with Santa Clara County. The wildfire impact analysis and Mitigation Measure WF-1 were refined in response to Draft EIR comments and additional public input. Additionally, Mitigation Measure GHG-1 was refined to provide flexibility in offsetting greenhouse gas emissions. Mitigation Measure NOI-3 was refined based on the revised noise analysis which was updated based on Project Description changes.

All written comments received on the adequacy of the ~~this~~ Draft EIR and Partially Recirculated Draft EIR during the public review periods are ~~will be~~ addressed in ~~a~~ "response to comments" chapters in ~~the~~ this Final EIR (Chapters 7 and 8). The response to comments and Final EIR will also present ~~any~~ changes to the Draft EIR resulting from public and agency comments, and Valley Water staff-initiated changes.

Text changes to the Draft EIR or Recirculated Draft EIR are shown in this Final EIR in underline (new text added) and ~~strikeout~~ (deleted text) format. Occasional changes to figures are shown by inserting new figures and striking out the prior figures. Appendices are not included in underline and strikeout to improve readability.

As previously mentioned, the revisions to the Project and alternatives descriptions in the Final EIR do not change the fundamental nature or main features of the Project or alternatives None of the comments, responses, or Final EIR revisions constitute "significant new information" that would require further Draft EIR recirculation under CEQA Guidelines Section 15088.5. Commenting agencies will receive a notice of the Final EIR's availability, including proposed responses to their comments and proposed revisions to the EIR, at least 10 days before Project approval.

Prior to any decision on the Project, the Board will review the Final EIR and consider certifying the document and approving the Project or an alternative at a regularly scheduled Board meeting. Prior to making a decision on the Project, the Valley Water Board must certify that: (1) the Final EIR has been completed in compliance with CEQA, (2) the Final EIR was presented to the decision-making body of the lead agency (Valley Water Board), and (3) the decision-making body (Valley Water Board) reviewed and considered the information in the Final EIR prior to approving a project (CEQA Guidelines Section 15090). ~~Upon EIR certification, Valley Water may proceed with Project approval actions. Approval of the Project would be preceded by~~ Following EIR certification, the Valley Water Board would then consider adopting written findings for each significant adverse environmental effect identified in the EIR (*CEQA Guidelines* Section 15091)~~, and if necessary,~~ and a statement of overriding considerations (*CEQA Guidelines* Section 15093). At the time that CEQA findings are adopted, Valley Water would also adopt a mitigation monitoring and reporting program for adopted mitigation measures. Descriptions of these documents are as follows:

- **Findings/Statement of Overriding Considerations.** For each significant impact of the Project identified in the EIR, Valley Water must find, based on substantial evidence, that either: (1) the Project has been changed to avoid or substantially reduce the magnitude of the impact, (2) changes to the Project are within another agency's jurisdiction and such changes have or should be adopted, or (3) specific economic, social, or other considerations make the mitigation measures or Project alternatives infeasible (CEQA Guidelines Section 15091). A Statement of Overriding Considerations must be adopted for significant unavoidable impacts that sets forth the specific social, economic, or other reasons supporting the agency's decision (CEQA Guidelines Section 15093).
- **Mitigation Monitoring Reporting Program.** CEQA requires the lead agency to adopt a Mitigation Monitoring and Reporting Program for mitigation measures that are adopted to avoid or substantially lessen significant effects on the environment. (CEQA Guidelines Section 15097[a]).

After these actions, Valley Water would consider whether to approve the Project or an alternative. If the Board decides to certify the EIR and approve the Project or an alternative, Valley Water would then file a Notice of Determination.

1.8 Organization of this ~~Draft~~ Final Environmental Impact Report

This ~~Draft~~ Final EIR contains the following components:

***Executive Summary*.** Summaries of the Project, Project alternatives, environmental impacts, and mitigation measures are provided in this chapter.

Chapter 1, Introduction. This chapter describes the Project background, EIR purpose and organization, and EIR preparation and review process.

Chapter 2, Project Description. This chapter describes the Project, including a brief description of the Project's location, the Project's purpose and dam safety requirements, the Project's objectives, Project components, Project construction approach and activities, updated dam and reservoir operational rule curves, and the AMP.

***Chapter 3, Regulatory and Environmental Setting and Impact Analysis*.** Chapter 3 includes 22 sections that describe existing regulatory and environmental conditions and the Project's anticipated environmental impacts. The introduction to Chapter 3 (Section 3.0) also discusses potential Project impacts that were dismissed from further analysis, including dismissed resource topics (e.g., mineral resources and population and housing). The following resource topics are addressed in Chapter 3:

- 3.1 – Aesthetics
- 3.2 – Agriculture and Forestry Resources
- 3.3 – Air Quality
- 3.4 – Biological Resources – Fisheries
- 3.5 – Biological Resources – Botanical/Wildlife
- 3.6 – Cultural Resources
- 3.7 – Energy
- 3.8 – Geology and Soils
- 3.9 – Greenhouse Gas Emissions
- 3.10 – Hazards and Hazardous Materials
- 3.11 – Hydrology
- 3.12 – Groundwater Resources
- 3.13 – Water Supply
- 3.14 – Water Quality
- 3.15 – Land Use and Planning
- 3.16 – Noise and Vibration
- 3.17 – Public Services
- 3.18 – Recreation
- 3.19 – Transportation
- 3.20 – Tribal Cultural Resources
- 3.21 – Utilities and Service Systems
- 3.22 – Wildfire

These resource sections also identify feasible mitigation measures to address impacts determined to be significant. This chapter also includes a discussion of the approach to cumulative impacts analyses and addresses the Project's potential to contribute to cumulative impacts at the end of each resource section.

Chapter 4, Other Statutory Requirements. Chapter 4 also outlines the Project's potential to induce growth and identifies irreversible environmental changes and significant unavoidable impacts resulting from the Project.

Chapter 5, Alternatives. This chapter describes the process through which alternatives to the Project were developed and screened, describes the alternatives selected for detailed evaluation, evaluates their likely environmental impacts, and identifies the environmentally superior alternative.

Chapter 6, Report Preparation. This is a list of the individuals involved in preparing the EIR and their responsibilities.

Chapter 7: Draft EIR Comments and Responses. This chapter contains public comments received on the Draft EIR and responses to those public comments.

Chapter 8: Partially Recirculated Draft EIR Comments and Responses. This chapter contains public comments received on the Partially Recirculated Draft EIR and responses to those public comments.

Appendices. The appendices to the EIR provide additional, often more technical or specialized information about various environmental topics discussed in the EIR.

Appendix A	Best Management Practices and Santa Clara Valley Habitat ~~Conservation~~ Plan Conditions, Avoidance and Minimization Measures, and Mitigation Measures ~~Incorporated in the Project~~

Chapter 2
PROJECT DESCRIPTION

2.1 Introduction

The proposed Seismic Retrofit of Anderson Dam would involve retrofitting and upgrading the dam and associated facilities to meet public safety requirements. The Project would also include the decommissioning of the hydroelectric facility at the dam to reduce operating costs, implementing conservation measures to offset Project impacts, and continuing to operate and maintain the dam after retrofit.

This chapter describes the Project. Topics included in this chapter are:

- Project location (Section 2.2)
- Project purpose, objectives, and benefits (Section 2.3)
- Overview of Project ~~project~~ components (Section 2.4)
- Seismic Retrofit construction (Section 2.5)
- Conservation Measures construction (Section 2.6)
- Construction phase monitoring (Section 2.7)
- Post-construction Anderson Dam facilities operations and maintenance (Section 2.8 ~~2.7~~)
- Post-construction Conservation Measures operations and maintenance (Section 2.9 ~~2.8~~)
- Project ~~ADSRP~~ and FAHCE Adaptive Management Program (Section 2.10 ~~2.9~~)
- Avoidance and Minimization Measures (Section 2.11 ~~2.10~~)
- Permits, approvals, and consultations (Section 2.12 ~~2.11~~)

The environmental impacts of each of these topics are analyzed in the various sections of Chapter 3, *Environmental and Regulatory Setting and Impact Analysis*.

2.2 Project Location

2.2.1 Regional Area – Coyote Creek Watershed

The Coyote Creek Watershed is the largest watershed in Santa Clara County,[1] encompassing an area of over 320 square miles. The headwaters of the Coyote Creek Watershed are on the east side of the county in the Diablo Range, originating on the slopes of Mount Sizer near Henry Coe State Park. The creek travels north and west across approximately 42 miles of the Santa Clara Valley floor, flowing into the San Francisco Bay south of Fremont and north of Milpitas (near Dixon Landing Road and Mud Slough) (**Figure 2-1**). Milpitas, and portions of San José and

[1] The geographic area of Santa Clara County is referred to herein as "the county." The governmental jurisdiction of the County of Santa Clara is referred to herein as "the County."

Morgan Hill, lie within the watershed boundaries, with the remaining watershed consisting of unincorporated lands within Santa Clara County.

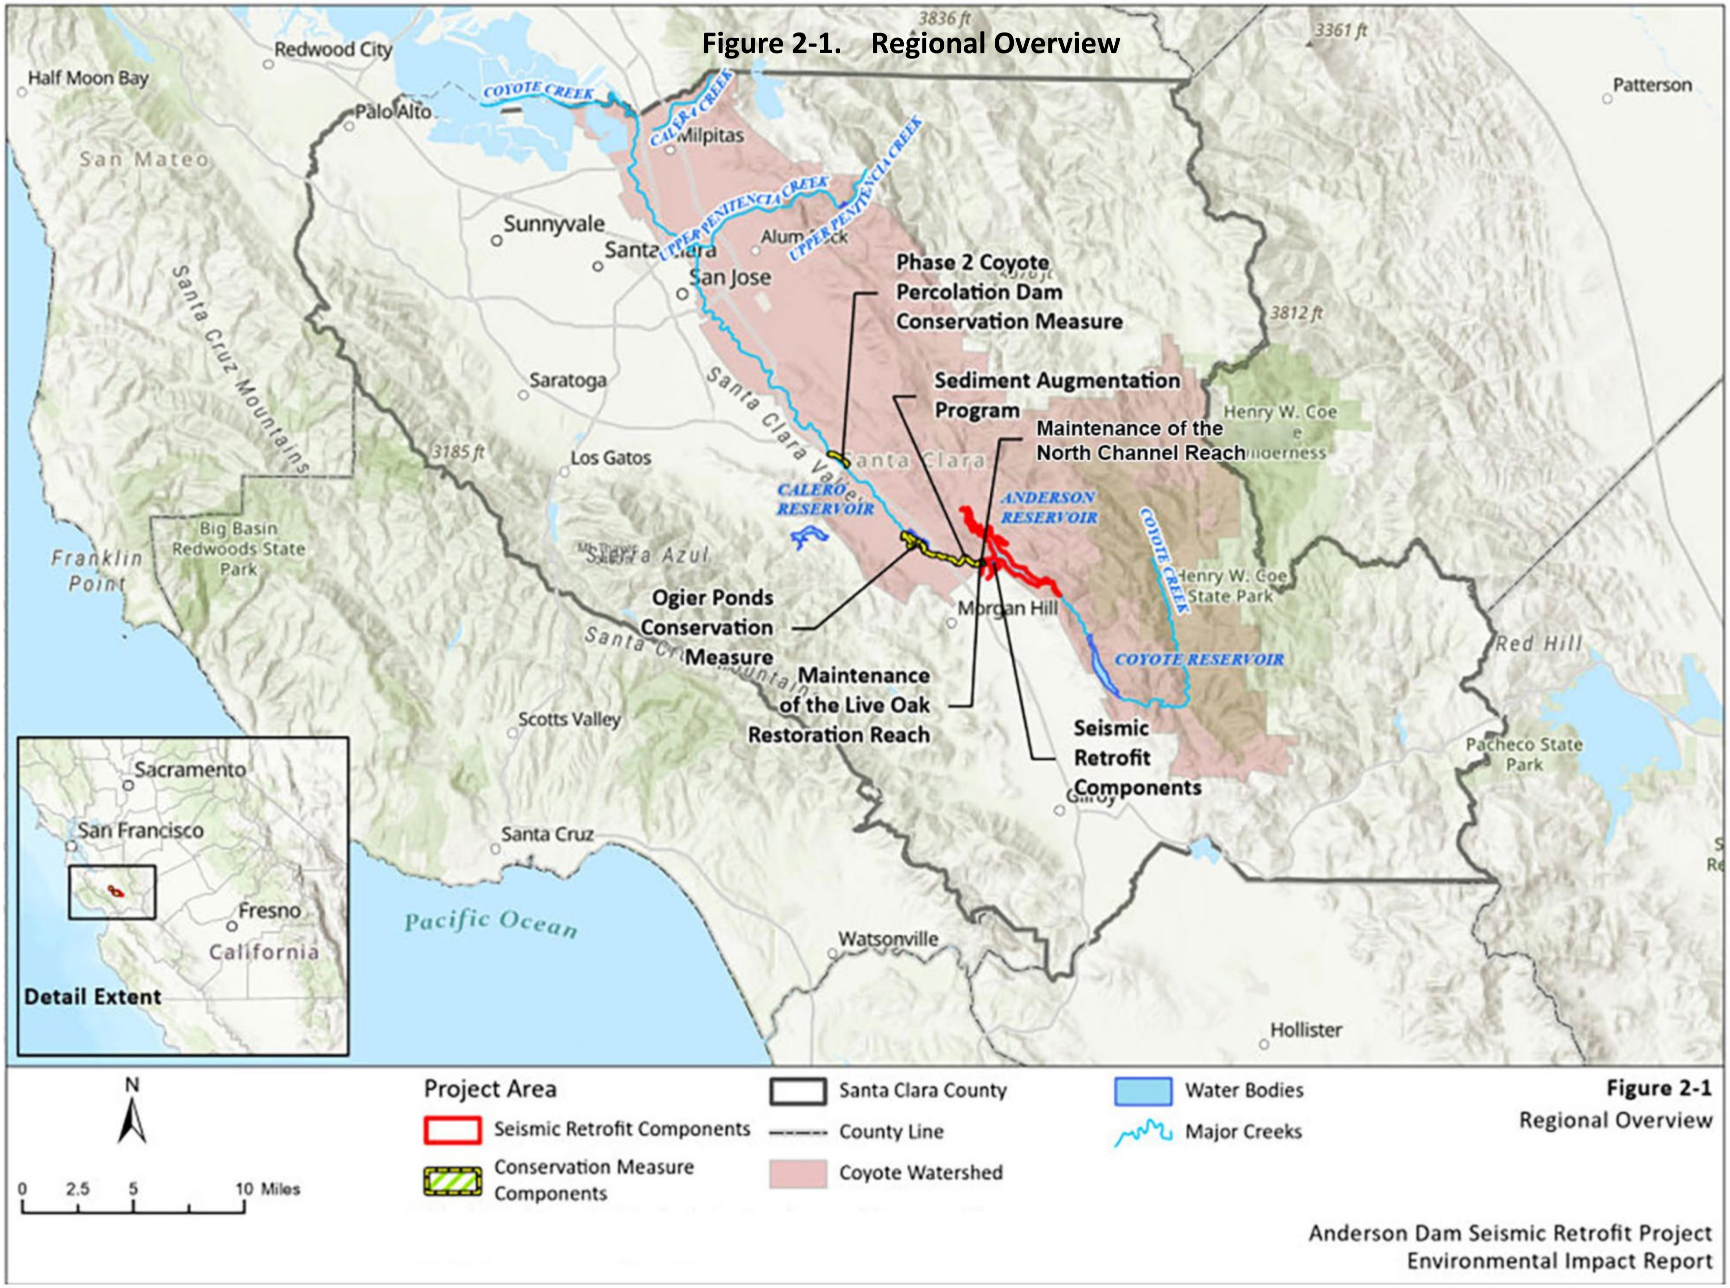
There are two water supply reservoirs owned by Valley Water along Coyote Creek: Anderson and Coyote (**Figure 2-1**). Anderson Reservoir, constructed in 1950, is a 235 -foot-high earthen dam that measures 1,430-feet long by 900-feet wide and sits on the Coyote Creek-Range Front Fault. It holds over 89,000 AF of water when full, with a surface area of 1,253 acres, more than all the other Valley Water surface water reservoirs combined. Coyote Reservoir is a 140-foot-high, 980-foot-long, earth and rock dam built in 1936 and holds 2,541 AF of water when full with a surface area of 633 acres. Because Coyote Reservoir is approximately 1.5 miles upstream of Anderson Reservoir, its normal operations, together with other inflows in the tributary area, affect flows into Anderson Reservoir. Winter runoff is stored in Coyote Reservoir and released during the dry season.

Anderson Dam impounds surface water runoff from the 195 square miles of the Coyote Creek Watershed, which includes inflow from several tributaries and releases from Coyote Reservoir, which is approximately 1.5 miles upstream of Anderson Reservoir. The upstream reaches of Coyote Creek and the watershed that feed into Anderson Reservoir are largely undeveloped. The contributing streams to Anderson Reservoir include Upper Coyote Creek, Las Animas Creek, Packwood Creek, and other small streams that drain directly into the reservoir (**Figure 2-1** and **Figure 2-2**). Downstream of Anderson Dam, Coyote Creek flows approximately 37.5 miles north-northwest through many densely urbanized areas in Santa Clara County, before ultimately reaching San Francisco Bay. Valley Water manages aquifer recharge using local water supply and imported water releases to Coyote Creek below Anderson Dam via the CDL and Cross Valley Pipeline.

Coyote Creek downstream of Anderson Dam has approximately 10 primary tributaries, the largest of which is Upper Penitencia Creek. Upper Penitencia Creek originates in the Diablo Range, several miles above Cherry Flat Reservoir (**Figure 2-2**). Historically, Upper Penitencia Creek did not have a hydrologic connection to the bay until an extension to Coyote Creek was constructed in 1876 (Santa Clara Basin Watershed Management Initiative [SCBWMI] 2001). Hydrology in the Upper Penitencia Creek Watershed is affected by the Penitencia Creek percolation ponds and by Cherry Flat Dam, a 500-AF dam, owned by the City of San José that detains water from 2.4 square miles of the 24-square-mile Upper Penitencia Creek Watershed. When available, Valley Water augments flow in Upper Penitencia Creek using imported water delivered through the DWR South Bay Aqueduct to provide on and off-channel recharge, mostly during periods when the creek would otherwise be dry.

The portion of Coyote Creek from Anderson Dam to San Francisco Bay and Upper Penitencia Creek from Cherry Flat Reservoir to the confluence of Coyote Creek is deemed critical habitat for Central California Coast (CCC) steelhead (*Oncorhynchus mykiss*), which is listed as threatened under the Endangered Species Act (ESA). Additionally, hatchery stray, Central Valley fall-run Chinook salmon (*Oncorhynchus tshawytscha*; Federal Species of Concern and State Species of Special Concern) may use reaches of Coyote Creek.

Figure 2-1. Regional Overview



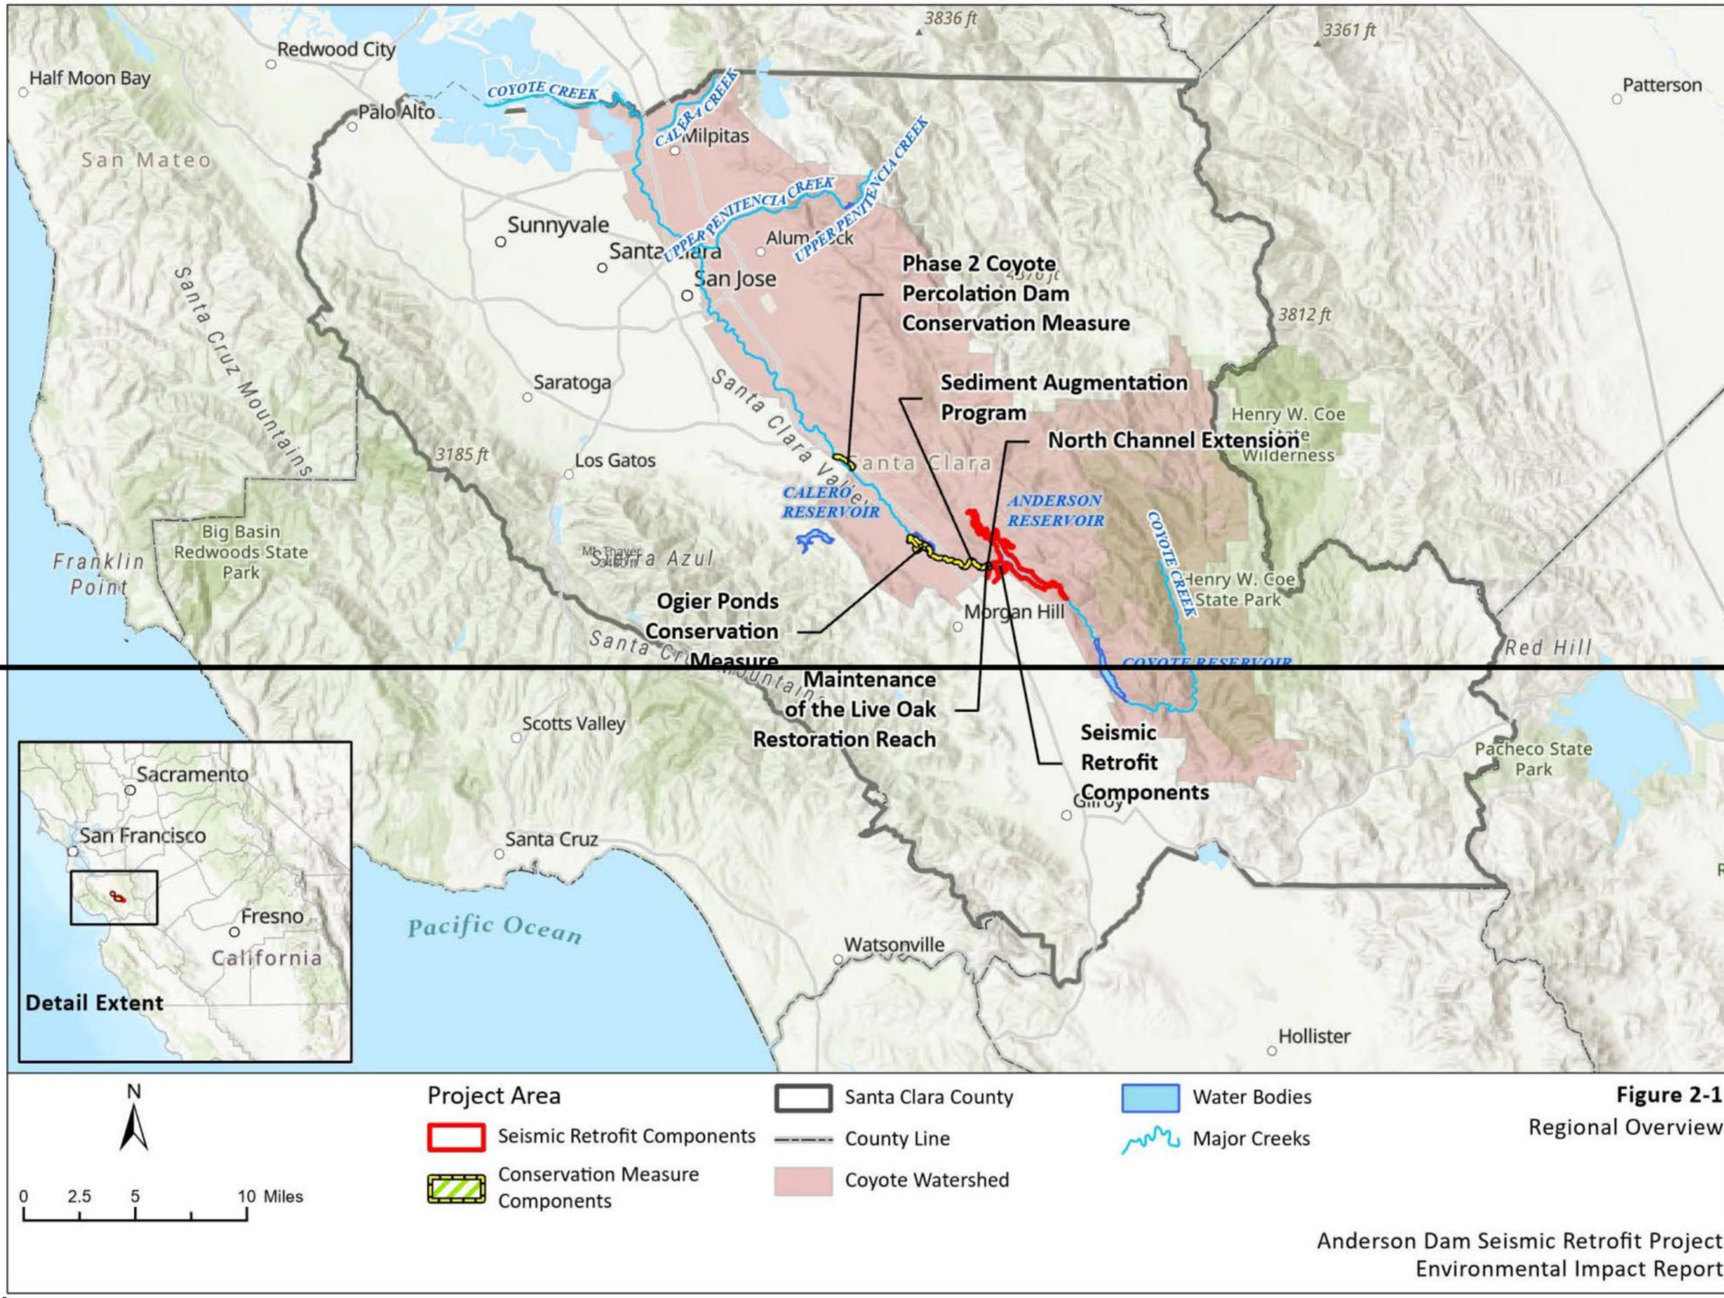


Figure 2-1
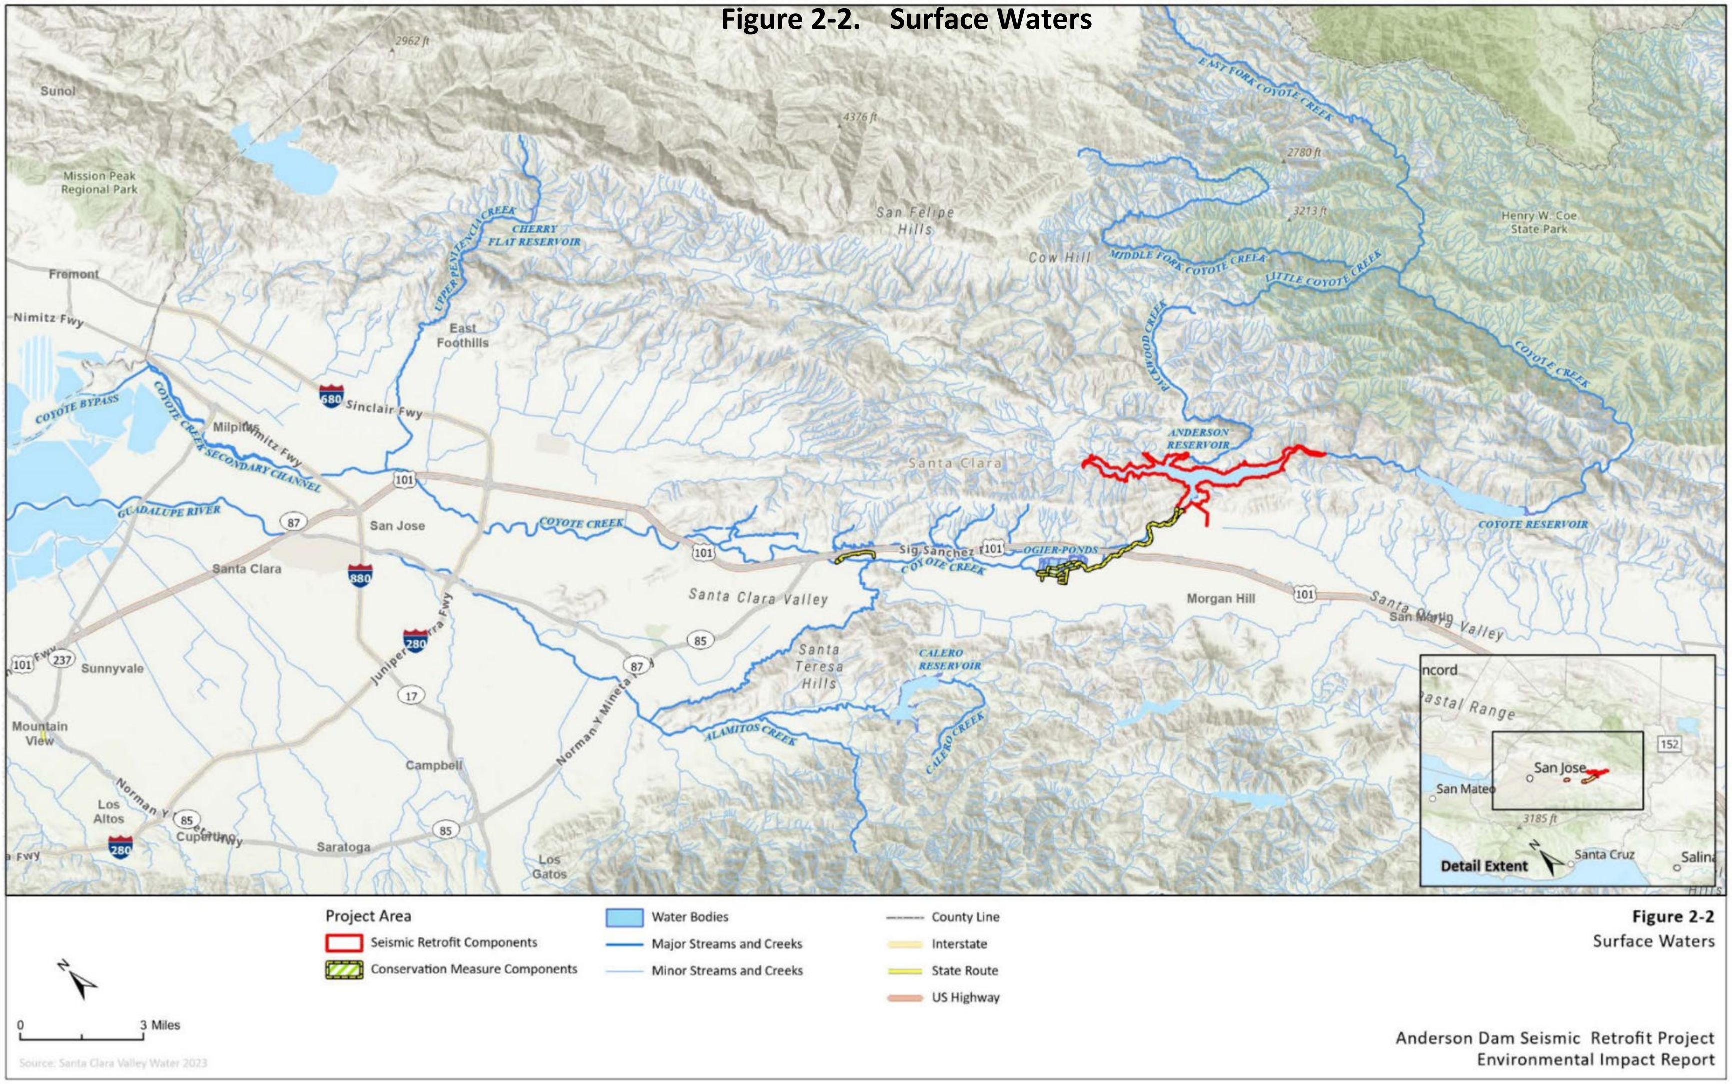
Regional Overview

Figure 2-2. Surface Waters



2.2.2 Project Area – Anderson Dam and Reservoir, Coyote Creek, Ogier Ponds, and Coyote Percolation Pond

Anderson Dam is located near the junction of Cochrane Road and Coyote Road in Santa Clara County, California, 0.8 miles east of U.S. Highway 101 (US 101) (Cochrane Road exit). It is 18 miles southeast of downtown San José, and 2.5 miles northeast of downtown Morgan Hill (**Figure 2-1**). Anderson Reservoir is located on lands within unincorporated Santa Clara County, Morgan Hill, and San José (Santa Clara County 1994, City of Morgan Hill 2017, City of San José 2023 ~~2020~~).

For the purposes of this EIR, the Project Area refers to the area and immediate vicinity within which all construction-related activities or ground disturbance would occur and the areas and facilities that would be operated through the implementation of the Project. The Project Area includes Anderson Reservoir, Anderson Dam, and other Seismic Retrofit Components; ~~North Channel Extension;~~ Sediment Augmentation Program; Ogier Ponds (approximately 4 miles downstream of Anderson Dam); maintenance of the North Channel and Live Oak Restoration reaches; the Coyote Percolation Dam (approximately 10 miles downstream of Anderson Dam); and lands in the immediate vicinity of Anderson Reservoir and Coyote Creek that are owned by Valley Water and the County of Santa Clara, as well as portions of the Cochrane Road and Coyote Road rights-of-way (**Figure 2-3a** and **Figure 2-3b)**. The Project Area also includes the Coyote Creek channel from Anderson Dam to the Coyote Percolation Dam. All proposed construction staging areas, borrow areas, stockpile areas, disposal areas, parking areas, and “off-street” access roads are also included in the Project Area (**Figure 2-4**).

The Project Area includes the cold water ~~coldwater~~ management zone (CWMZ), an approximately 6~~5~~ mile stretch of Coyote Creek between the Anderson Dam outlets and Coyote Creek Golf Drive, as defined in the FAHCE *Settlement Agreement* (2003). ~~Within this~~ This stretch of Coyote Creek encompasses ~~there is~~ the majority of the ~~potential for effects to occur to~~ ESA-listed steelhead *(O. mykiss)* rearing and spawning habitat in Coyote Creek. It is also the stretch where adverse impacts from the Project on fisheries resources would be most concentrated and where the majority of the conservation measures occur. However, there are also impacts and conservation measures downstream of this stretch, within the fisheries resources study area that are addressed throughout the impact analysis as well ~~as a result of Anderson Dam operations~~. The intersection of Coyote Creek with Coyote Creek Golf Drive occurs downstream of the Ogier Ponds. The existing physical conditions within this lower reach of Coyote Creek reduce habitat suitability for *O. mykiss* downstream of the ponds. As such, the current functional cold water management zone (FCWMZ) effectively ends at the upstream end of Ogier Ponds, 4 miles downstream from Anderson Dam. In this EIR, the FCWMZ refers to the reach between Anderson Dam and Ogier Ponds, and is the area that ~~is~~ currently contains the most known suitable spawning and rearing habitat for *O. mykiss*. With the completion of the Ogier Ponds Geomorphic and Habitat Restoration Conservation Measure (Ogier Ponds CM) that includes creek pond separation (Section 2.6.1.), it is anticipated that the 6- ~~5-~~mile CWMZ would be restored within Coyote Creek to Coyote Creek Golf Drive.

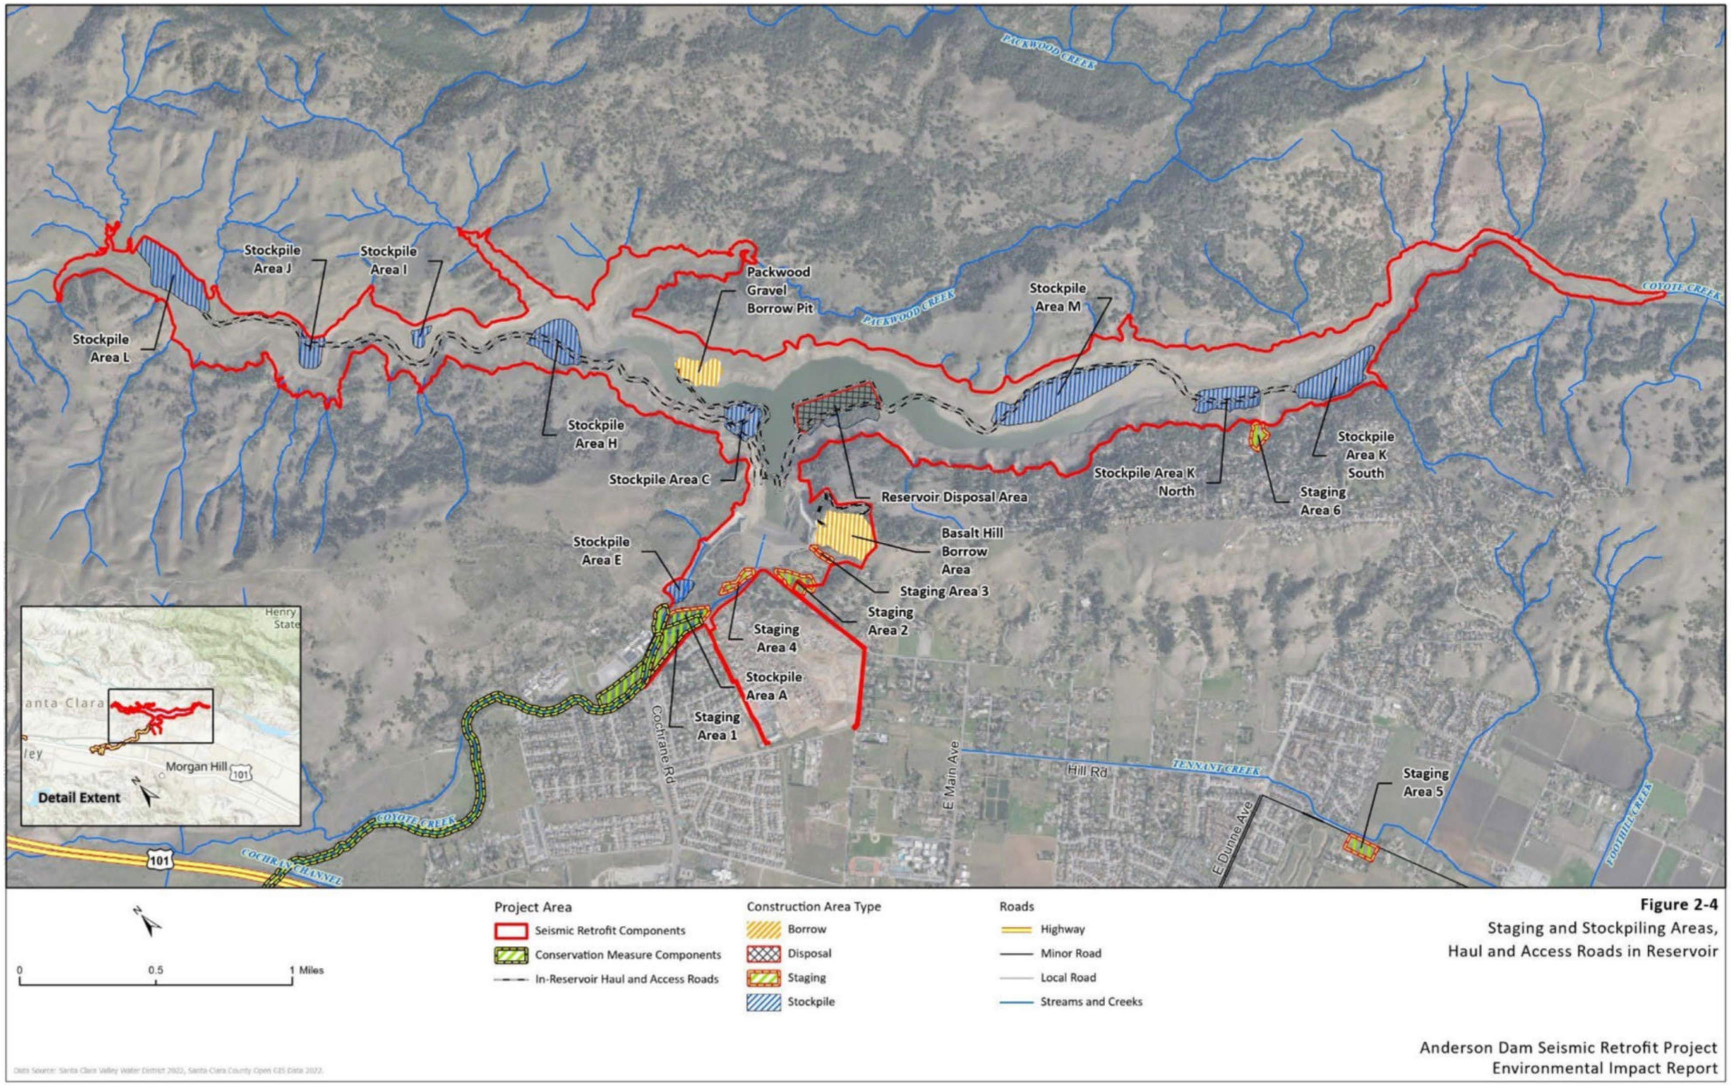
Figure 2-4.. Staging and Stockpiling Areas, Haul and Access Roads in Reservoir



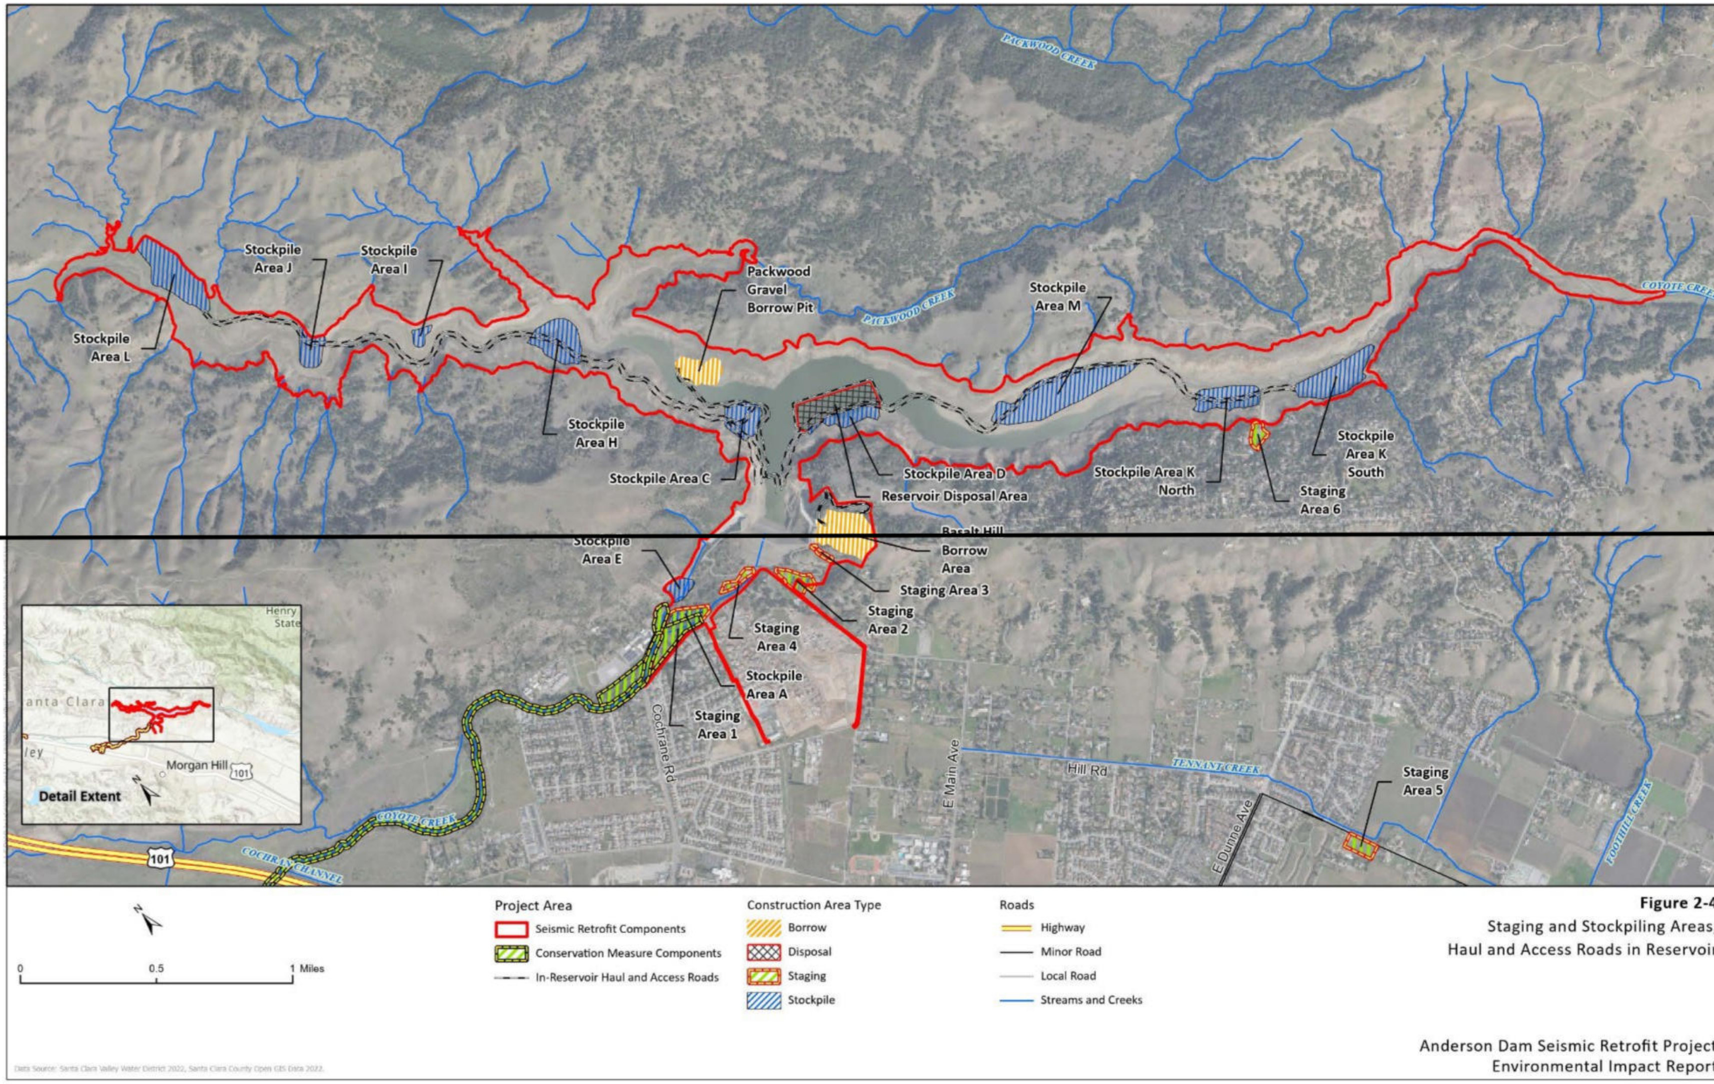


Figure 2-4
Staging and Stockpiling Areas, Haul and Access Roads in Reservoir

2.2.3 Surrounding Land Uses

Existing land uses within and adjacent to the Project Area include areas of parkland. Surrounding Anderson Reservoir, the Anderson Lake County Park has many features, including the Anderson Reservoir boat ramp, multiple picnic areas, Anderson Lake Visitor's Center, Serpentine Trail, Lakeview Trail, and Rancho Laguna Seca Trail. Other land uses around the reservoir include grazing lands and single-family residences (both rural and suburban).

Downstream of Anderson Dam, Anderson Lake County Park adjoins the Coyote Creek Parkway, approximately 1 mile downstream of Anderson Dam. Coyote Creek Parkway encompasses Coyote Creek downstream to approximately 15 miles and contains a number of paved and unpaved multi-use trails that connect Anderson Lake County Park with Hellyer County Park. This area also includes a variety of recreational amenities, including picnic and rest areas, Ogier Ponds, and a model airplane field. This area also supports orchard lands, the Santa Clara County Justice Training Center and William F. James Boys Ranch. Coyote Creek Parkway includes the Coyote Creek Trail that runs adjacent to the footprint of Coyote Creek. Coyote Creek Trail extends from the San Francisco Bay to the northern end of Morgan Hill. The Coyote Creek Trail runs through and adjacent to the Project Area, from Anderson Lake Visitor Center to the southern end of Ogier Ponds.

2.3 Project Purpose, Objectives, and Benefits

2.3.1 Project Purpose

The purpose of the Project is to seismically retrofit, maintain, and operate Anderson Dam and Reservoir to meet FERC and DSOD safety requirements, thereby allowing Valley Water to maximize water supply and related incidental benefits, while avoiding and minimizing environmental impacts of the implementation of those safety directives and requirements. Without such regulatory compliance, Valley Water would be required to maintain a very low water level in Anderson Reservoir, that would in turn reduce water supplies that would otherwise be available for water supply deliveries to treatment plants, managed groundwater recharge, and maintenance of a local source of emergency water supply. Valley Water would likely have to replace those lost supplies to achieve its water supply and management goals that may result in significant cost increases, to the extent that any alternative resources are available.

FERC and DSOD requirements that pertain to the Project are described below.

2.3.1.1 FERC Requirements

Per FERC requirements, the Project addresses seismic deficiencies of the dam, specifically providing a stable dam embankment capable of withstanding MCEs on the Calaveras and Coyote Creek Range Front Faults. In addition to the seismic deficiencies of the dam, presently the spillway lacks the capacity to safely pass the flood flows related to passage of a PMF event. An updated PMF evaluation completed in 2013 (HDR 2013) predicts a peak spillway discharge of 95,800 cubic feet per second (cfs) at a reservoir stage of elev. 652.5 feet during a PMF. The PMF flow exceeds the current spillway capacity by 50 percent and would cause overtopping of the existing dam embankment by several feet. Overtopping of the dam could lead to dam failure.

FERC (as well as DSOD) dam safety criteria require that spillways be sized to safely pass PMF flows without overtopping the dam. Consequently, the spillway would be modified and improved, in conjunction with raising of the dam crest, to address this deficiency.

2.3.1.2 DSOD Requirements

DSOD requires the new outlet works at Anderson Reservoir to be capable of lowering the reservoir's maximum storage depth by 10 percent within 7 days and draining its full content within 90 days (DSOD 2018 ~~2017~~), even if a fault offset were to occur. DSOD also requires that the entire spillway (including the currently unlined portion of the spillway) to be able to contain the PMF, and will require deepening and hardening of the unlined portion in order to mitigate the risk of spillway failure in the event of a PMF (DSOD 2021).

2.3.2 Project Objectives

The objectives of the Project, consistent with FERC and DSOD dam safety requirements, are to:

1. Seismically retrofit and maintain the dam so that Valley Water may continue to operate it at capacity. This objective would be achieved by:
   - Replacing the existing dam to withstand the MCEs on the Calaveras and Coyote Creek Range Front Faults
   - Replacing the existing spillway to meet FERC and DSOD safety requirements related to the safe passage of a PMF
   - Replacing the outlet works to meet current DSOD outlet works requirements and accommodate fault offset
2. Improve cost efficiency of dam operations by decommissioning the hydroelectric facility
3. Avoid and minimize environmental effects of construction and operations.

2.3.3 Project Benefits

Implementation of the Project components, including the Conservation Measure, would result in a more seismically safe dam that would allow Valley Water to better carry out water supply and groundwater recharge activities. Operational flexibility would also be improved by the Project that would:

- minimize the risk of reservoir spills and downstream flooding
- provide in-stream environmental flows consistent with regulatory requirements
- restore recreational opportunities at Anderson Reservoir and along the Coyote Creek corridor

2.4 Overview of Project Components

The Project consists of numerous Project ~~project~~ components that fall into six over-arching categories:

1) **Seismic Retrofit Components:** Project components related to the Anderson Dam facility upgrades and improvements to stabilize and mitigate potential seismic risks and comply with current public safety requirements.

2) **Conservation Measure Components:** Project components designed to avoid and minimize adverse environmental impacts, and in some cases provide environmental benefits. These Project components would be implemented throughout Project construction and/or operation phases. These measures would reduce construction-related impacts and allow for managed aquifer recharge to support water supply requirements, while improving and maintaining wetted habitat for fish, wildlife and other groundwater-dependent habitats. Many of these Project components align with the FAHCE Phase 1 non-flow measures, as described in FHRP, and would provide improved fish passage, steelhead spawning and rearing habitat, and restored hydrologic functions.

3) **Construction Monitoring:** Project components include habitat and species monitoring during construction to document project effects on the environment.

4) **Post-Construction Anderson Dam Facilities Operations and Maintenance:** Project components that involve how proposed, permanent Anderson Dam facilities would be operated and maintained following construction. These Project components include implementation of the FAHCE Phase 1 flow measures at the Anderson Dam facility, post-construction monitoring, and post-construction maintenance.

5) **Post-Construction Conservation Measure Operations and Maintenance:** Project components that involve how proposed, permanent Conservation Measure facilities would be operated and maintained following construction. These Conservation Measure facilities include implementation of the Ogier Ponds CM, maintenance of the North Channel and Live Oak Restoration reaches, ~~North Channel Extension,~~ Phase 2 Coyote Percolation Dam Fish Passage Enhancements (Phase 2 Coyote Percolation Dam CM), and the Sediment Augmentation Program.

6) **Post-Construction Project and FAHCE Adaptive Management Program**: Adaptive management of all post-construction operations, and all habitat restoration Conservation Measures components would occur in accordance with the FAHCE AMP. Pursuant to the FAHCE Framework, a Project-specific ADSRP AMP has been developed. The AMP includes four key elements: measurable objectives for steelhead and salmon fisheries and their habitats; compliance monitoring, validation monitoring, effectiveness monitoring, and long-term trend monitoring; adaptive actions that may be identified to assure measurable objectives are met; and reporting.

Table 2-1 provides a detailed summary of each Project component, as organized under the six over-arching categories described above. **Table 2-1** includes columns that summarize the Project ~~project~~ component and purpose, activities that would occur during the construction phase of the component, and/or activities that would occur during the post-construction (operations and maintenance) phase of the Project. Where appropriate, text is included that directs the reader to sections(s) where construction, operations, and maintenance activities are described in greater detail. Additionally, **Table 2-1** includes a column that identifies figures or figure sets where the Project component(s) are identified, illustrated, and/or depicted.

1 **Table 2-1. Project Components**

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
Seismic Retrofit (Refer to Figure 2-3a, Anderson Dam Seismic Retrofit Overview Map)				
Dam Embankment	Removal and replacement of the existing dam to withstand MCEs on the Calaveras Fault and Coyote Creek Range Front Fault. The replacement dam would be placed at the same location as the existing dam.[2] All but a portion of the existing dam's clay core (approximately 500 feet across, 10 feet wide, and 50 feet tall) would be excavated and replaced systematically to create a zoned embankment dam. The zones would include a clay central core zone placed over the remnant core, and have adjacent filter (sand), drain (gravel), and transition-zones, and relatively coarse-grained shells. The completed replacement dam would have a crest length of approximately 1,700 feet and a crest height of elev. 656 feet.	Dam excavation and reconstruction involves a multi-stage construction process, described in Section 2.5.	Post-construction maintenance of Anderson Dam facilities is described in Section 2.8.	None
Dam Crest	Increase in height of the existing dam crest (from elev. 647.9 to elev. 656 feet) to accommodate the PMF. The replacement dam would also include 4 feet of camber (i.e., overbuild) in the central portion of the dam and less near the dam abutments to accommodate anticipated post-construction settlement. The dam crest would retain its current width of approximately 40 feet and would be paved for Valley Water and County personnel vehicular access.	Retrofitting the dam and raising the dam crest involves a multi-stage construction process, fully described in Section 2.5.4.	Post-construction maintenance of Anderson Dam facilities is described in Section 2.8.5.	None
Spillway	Removal and replacement of the existing spillway to accommodate safe passage of the PMF (i.e., 95,800 cfs). The existing spillway is situated on the right abutment (north side) of the dam. It is ungated, with a 223-foot-long ogee crest, and an 860-foot-long concrete-lined chute that terminates in a dentated flip bucket. The concrete-lined chute has a width of 150 feet at the upstream end and 100 feet at the downstream end. At the downstream end of the chute, the spillway drops off vertically about 20 feet (elev. 520 feet) into an unlined spillway channel that terminates at a 70-foot waterfall (Valley Water 2021a). The replacement spillway would be located within the same general footprint occupied by the existing spillway and unlined spillway channel; however, the new spillway would be fully lined. The new spillway crest would have the same length, elevation (elev.627.9 feet), and generally the same shape as the existing spillway. Because the spillway crest elevation would be unchanged, the capacity of Anderson Reservoir would also not change due to a difference in the maximum water surface elevation[3].	Construction of the new spillway would involve removal of most of the existing spillway concrete except a small portion underlying the right chute wall at the right end of the existing spillway crest. Construction required for spillway replacement is described in Section 2.5.4.	Several of Project components, including the modified spillway, would allow for the implementation of FAHCE rule curves, described in Section 2.8.3. Post-construction maintenance of Anderson Dam facilities is described in Section 2.8.5.	None
Temporary Diversion Systems	Conversion of the Stage 1 Diversion System (also known as the Anderson Dam Tunnel, which was previously constructed as part of the FOCP) to the Stage 2 Diversion System would reduce the risk of interim embankment overtopping during dam construction. The Stage 2 Diversion System consists of most of the Stage 1 Diversion System except a portion at the upstream end, with the addition of a cofferdam and an extension pipe within the reservoir that would allow the storage level to lower to elev. 453. The ~~screened~~ intake structure and tunnel constructed during conversion to Stage 2 would replace the lake tap pipe and trash rack of the Stage 1 Diversion System. The cofferdam would be constructed upstream of the embankment work area to intercept	Construction associated with the temporary diversion system is described in Section 2.5.4.	Because the diversion systems would be converted into the LLOW and HLOW prior to completion of Project construction, there is no additional operation and maintenance involved with this Project component.	Figure 2-5 Existing Stage 1 Diversion System Figure 2-6 Proposed Stage 2 Diversion System

[2] The replacement dam would have a footprint (37 acres) that is larger than the existing dam (29 acres).
[3] The current capacity of 89,278 AF has been reduced from its original capacity by an estimated 1,790 AF due to sediment accumulation (Valley Water, 2020a). Over the duration of the Project, a portion of the accumulated sediment would be transported out of the reservoir area during diversion of reservoir inflows around the construction area resulting in some recovery of lost reservoir capacity. The volume of recovery depends on the number and severity of storms that occur during the diversion period. Additionally, some storage would be lost due to in-reservoir disposal. When the <u>Project</u> ~~project~~ is completed, it is estimated that the reservoir will have a storage capacity of approximately 88,800 AF.

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
	reservoir inflow, which would be passed downstream via an extension pipe that connects to the diversion system intake. The area between the cofferdam and dam embankment would be fully dewatered during each construction season to create a dry work area.			
Outlet Works	Construction of outlet works along the right (northern) dam abutment (along the south side of the spillway) would include a HLOW and a LLOW. The LLOW would provide discharge capacity for normal operations, and the majority of the discharge capacity for emergency releases. The LLOW would be capable of simultaneously making releases to Coyote Creek and delivering flows to the Valley Water raw water transmission system through the Anderson Force Main (Valley Water 2021h ~~2023d~~). The HLOW would provide additional discharge capacity, in combination with the LLOW, in the event of an emergency.	Construction associated with the outlet works system is described in detail in Section 2.5.4.	The LLOW would be capable of releasing up to 1,485 cfs of water from the reservoir to Coyote Creek through the 78-inch conveyance pipeline (release capacity of 1,315 cfs) and the 33-inch bypass pipeline (release capacity of 170 ~~1,05~~ cfs). Having two pipelines within the LLOW allows Valley Water to simultaneously release water from the reservoir to the creek, while maintaining a connection with the raw water system (i.e., sending water to the treatment plants or pumping imported water into the reservoir). The HLOW would be used for dam releases that exceed the capacity of the LLOW system, up to a maximum flow capacity of 5,300 cfs, in the event of an emergency. The new outlet works, including valves, vaults, pipeline junctions, and appurtenances, would be maintained under the Dam Maintenance Program, which would include routine inspections, valve tests, repairs, and monitoring. Post-construction maintenance is described in Section 2.8.5.	Figure 2-7 High-level Outlet Works System Figure 2-8 Low-level Outlet Works System
Pipeline Realignments	Connections to existing Anderson Force Main and Main Avenue Pipelines. Connection to the existing underground 54-inch-diameter Anderson Force Main includes constructing 200 feet of new pipeline and either removing or abandoning in-place (e.g., fill with CLSM) a similar length of existing Anderson Force Main. Connection to the existing 36-inch diameter Main Avenue Pipeline includes constructing 375 feet of new pipeline and either removing or abandoning in-place (e.g., fill with CLSM) a similar length of existing Main Avenue Pipeline. Cathodic protection systems would also be installed.	Construction associated with pipeline realignment is described in Section 2.5.4.	Realignment and connections of the underground Anderson Force Main and Main Avenue Pipelines would be maintained in a manner consistent with the existing Valley Water DMP and PMP. Valves, vaults, pipeline junctions, and appurtenances at the LLOW would be maintained as part of the DMP, which would include routine inspections, annual tests, repairs, and monitoring. The Anderson Force Main and Main Avenue Pipelines would be maintained in accordance with the PMP, which includes scheduled maintenance, inspections, cathodic protection, and periodic dewatering. Pipeline dewatering of these pipe sections would be achieved though releasing water into Coyote Creek via the LLOW (Valley Water 2007, 2012). Post-construction maintenance is described in Section 2.8.5.	Figure 2-9 Proposed Pipeline Realignment
Communication Lines Beyond Dam Excavation Footprint	To improve and provide communication network connectivity in the Project Area, communication lines from Anderson Dam to Peet Road would be installed. Fiber optic lines would be installed and telemetry cables would be replaced. This Project component would consist of approximately 5,000 linear feet of trenching along Anderson Force Main. The communication line would provide network connectivity to Anderson Dam, the hydroelectric facility, and the Coyote Pumping Warehouse.	Construction associated with the telemetry cable replacement is described in Section 2.5.4.	Communication lines would be maintained in a manner consistent with the DMP.	Figure 2-10 Proposed Communication Lines
Temporary and Permanent Roadway Modifications	Existing roadways throughout the Project Area would be modified to accommodate improved and new Anderson Dam facilities. Permanent modifications include: (1) Coyote Road through the boat ramp parking area; (2) Coyote Road across the dam crest, (3) Coyote Road along the spillway; (4) addition of permanent access roads that lead to parking areas at the base of the dam, (5) addition of a new permanent access road on the downstream slope of the dam from Coyote Road to the right abutment to the high-level	Construction associated with roadway modifications is described in Sections 2.5.2.(temporary access roads) and 2.5.4. (permanent roadways).	Facility maintenance roadways and gates will be maintained in manner consistent with the DMP. Park access roadways would be operated and maintained by County Parks and would not require additional actions as part of the Project.	None

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
	outlet tunnel, and (6) the addition of a new permanent access road to the left bank of the Northern Channel downstream of the dam. Permanent roadway modifications are further described in Section 2.5.4. Temporary roadway modifications include adjusting (ADTP) access roads for hauling and accessing the dam and other construction areas during construction. Temporary access roads would be constructed along the upstream slope of the dam, downstream slope of the dam, and in the reservoir areas. Several temporary access roads would be constructed in the reservoir to access the Packwood Gravel Borrow Pit and stockpiles. The temporary access roads are further described in Section 2.5.2.			
Decommissioning of Hydroelectric Facility	Termination of connection and power generation of the existing built hydroelectric facility, located within Valley Water property along Cochrane Road to the west of Anderson Dam. Decommissioning would involve the disassembly, removal, and/or abandonment of two turbines and other aboveground and belowground mechanical and electrical equipment from the existing hydroelectric facility. This process would involve coordination with PG&E for the termination of connection between the existing facility and existing PG&E infrastructure related to power generation.	Construction, including disassembly, removal, and/or abandonment of facilities, associated with decommissioning of the hydroelectric facility is described in Section 2.5.4.	Once the existing hydroelectric facility has been decommissioned, this component would require no additional activities related to operation. The decommissioned facility would require minimal maintenance-related activities, including activities that would maintain the abandoned building to prevent dilapidation of the structure. This might include routine annual inspections, building maintenance and repair, trash and debris removal, and vegetation management.	None
Conservation Measures				
Normal Operation of Coyote Reservoir	Coyote Reservoir is approximately 1.5 miles upstream of Anderson Reservoir. Along with other inflows to Anderson Reservoir, its operation would affect flows through Anderson Reservoir during Project construction. Valley Water would maintain existing normal operations of Coyote Reservoir throughout the drawdown of Anderson Reservoir, and construction of the Seismic Retrofit components. By maintaining existing operations of Coyote Reservoir during construction of the FOCP and Project, Valley Water would partially retain the ability to store winter runoff in Coyote Reservoir and release it through Coyote Reservoir's outlet pipe to Coyote Creek to pass through Anderson Dam during the dry season, benefitting the native aquatic plants and animals that reside in this reach. As seismic retrofit construction progresses, all Coyote Reservoir releases would pass through the existing Anderson Dam outlet, through the Stage 1 Diversion System, through the Stage 2 Diversion System, and finally through the LLOW. Valley Water aims to maintain a minimum streamflow of 3 to 5 cfs at Gage SF12 (downstream of Coyote Reservoir) through releases from Coyote Reservoir in the spring and summer (when supply is available) and managing storage consistent with ~~in~~ the ~~winter to stay within~~ DSOD restriction established in 1992. Full capacity of the Coyote Reservoir outlet would be used when ~~restrictions (maximum~~ storage in Coyote Reservoir exceeds ~~is~~ 11,843 AF, which corresponds to the DSOD restriction on water surface elevation of 758.0 feet in local datum or 760.9 feet in NAVD 88, to reduce storage in Coyote Reservoir to the DSOD-restricted level.~~).~~ Furthermore, no operational changes are proposed for Coyote Reservoir during post-construction operations. Flows between Coyote and Anderson Reservoirs within Coyote Creek would continue within current, normal ranges during the entirety of the Project.	None. This component involves continued operation of existing infrastructure and operations at Coyote Reservoir.	None. This component involves continuation of existing operations at Coyote Reservoir, which would continue to be maintained per the DMP.	Figure 2-1 Regional Overview Map, which identifies Coyote Reservoir

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
Construction Period Wet Weather Bypass and Dry Weather ~~Imported Water~~ Releases for FCWMZ (releases from CDL and Cross Valley Pipeline Extension, and Use of Chillers)	During construction, wet weather natural flows would be passed through or around the dam and dam work area to provide pulse and instream flows in Coyote Creek to support steelhead and salmon migration. During the dry weather periods of the construction phase, releases of available local water stored in Anderson reservoir (if any) would be supplemented by releases of imported water from the CDL and the Cross Valley Pipeline Extension. These supplemental releases would support instream flows, groundwater recharge and groundwater-dependent ecosystem management, as well as improved water quality, decreased energy costs, water supply management, support of native aquatic fish and wildlife habitat, and riparian vegetation. Valley Water would augment releases of local water using other sources of supply, including releases from the CDL and releases from the Cross Valley Pipeline Extension. Imported water would be released into Coyote Creek just below the dam via the CDL. The amount of flow released from the CDL would depend on the time of year, the temperature, the amount of local water available for release from the reservoir to mix with the imported water, and actual hydrology at the time of the release (10 to 65 cfs), with the target of having a minimum flow of 2.5 cfs at the Edenvale streamflow gage (SF5058). As part of the FOCP, Valley Water extended the Cross Valley Pipeline to allow for imported water releases downstream of Ogier Ponds. Releasing imported water below Ogier Ponds ensures that more reaches of Coyote Creek stay wetted, enables recharge of the Coyote Valley and South San José areas throughout the construction period, and supports the maintenance of aquatic habitats for wildlife and riparian vegetation. Augmented releases of imported water also reduce potential subsidence in downstream lands. The extension is designed to have the capacity to carry 67 cfs of imported water. To avoid the potential for improper fish attraction cues at the Cross Valley Pipeline Extension outfall, the Cross Valley Pipeline Extension releases would not occur during higher flows. Valley Water would cease Cross Valley Pipeline Extension releases when flows exceed 65 cfs at streamflow station 5082 and Coyote Creek at Madrone during the adult upstream migration season (December 1 to April 30), unless there is less than 2.5 cfs at streamflow station 5058, Coyote Creek Edenvale. During construction, if imported water releases are determined to be too warm for *O. mykiss*, chillers installed under the FOCP would be used to cool up to 10 cfs of imported water prior to release via the CDL into Coyote Creek within the FCWMZ, and additional imported water would be released via the Cross Valley Pipeline Extension downstream of Ogier Ponds to continue to provide groundwater recharge below the FCWMZ. A total of three chillers (two chillers would be used with a third chiller available in reserve) would take an 800-amp current to chill a combined flow of up to 10 cfs by 7°C to provide cooler temperature flow to the FCWMZ. More information is provided in Section 2.5.3.	None. Involves use of infrastructure that would be constructed as part of the FOCP.	This component would support temperature regulation of surface waters during construction of the Project. Imported water releases to occur following construction are described below (refer to "Post-Construction Imported Water Releases" below). Following construction of the Project, site restoration and short-term maintenance for the Cross Valley Pipeline Extension would involve activities for the control of invasive weeds, removal and replacement of dead plants, implementation of plant protection measures, installation of signage, irrigation supply and/or system maintenance, surficial erosion control, removal of trash and debris, and control for opportunistic invasive wildlife species. Long-term maintenance for the CDL and Cross Valley Pipeline Extension would be conducted under Valley Water's PMP and SMP, where activities would be conducted in a manner that is consistent with these existing programs. Both of these programs have their own environmental review, permitting, and mitigation processes. This includes the replacement of valves after 30 years, and an assessment of appurtenances every 10 years. Chillers and ancillary chiller plant equipment (constructed as part of the FOCP) would be decommissioned after the completion of the Project construction. The aboveground pipelines would be demolished, and the underground pipes would be abandoned in place. The chillers plant would be removed and stored at an offsite location.	None

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
Ogier Ponds CM[1]	The Ogier Ponds CM would separate Coyote Creek from Ogier Ponds. This conservation measure would provide ecological enhancements to the channel and floodplain, improve water temperature impacts of the ponds, enhance fish migration, and reduce fish entrainment, and integrate public access. The Ogier Ponds CM would consist of reconstructing the pre-1997 creek channel to create a geomorphically stable creek with a connected floodplain, adding habitat and biological features to the creek and floodplain. The new section of creek channel would start at the former location of Pond 1 and connect to the pre-1997 channel alignment located west of Ponds 2, 3, 4, and 5. The new channel alignment would be approximately 6,500 feet in length, reconnecting to the current Coyote Creek channel downstream of the Ogier Ponds complex. The floodplain total width along the new channel would range up to 700 ~~600~~ feet, all within the creek alignment. The Ogier Ponds CM would fill Pond 1 and construct two berms to create a new section of the creek channel and floodplain in the area of the pre-1997 creek channel. The Ogier Ponds CM would completely fill and remove ~~removal~~ Ponds 1 and 5, and~~,~~ partially fill Ponds 2, and 4, separating all of the ponds ~~3, and 5~~ from the restored channel except during high flow conditions. No changes are proposed at Ponds 3 and 6. A fish culvert would be installed to spill into Coyote Creek at Pond 4. Native vegetation would be planted in areas along the floodplain to create riparian habitat. Full description of this Conservation Measure component is provided in Section 2.6.1.	Construction of the Ogier Ponds CM is described in Section 2.6.1.	Maintenance activities required for this Project ~~project~~ component include invasive vegetation management, trash removal, and repair and replacement of berms, spillways, fish screens, in-channel bio-engineered habitat enhancements, rock slope protection, stormwater outfalls, and maintenance roads. Routine inspection of spillways, berms, fish screens, and stormwater outfalls would also be conducted. Operations activities for Ogier Ponds would involve allowing creek flows to flow through the pond only in certain circumstances. The spillway structure would be operated to divert flows from the restored channel to the ponds to protect the channel when flows exceed greater than 2,000 cfs. Monthly inspections would be conducted to monitor water quality changes. To maintain or improve DO in the ponds during normal conditions in the absence of creek flow-through, solar powered floating aerators would be installed to maintain or improve DO as compared to existing conditions. Other water quality best management practices may also be deployed, if necessary as indicated by pond water quality monitoring results to maintain or improve upon existing water quality conditions in the ponds. Full description of operation and maintenance activities necessary for this Conservation Measure component is presented in Section 2.9.2.	Figure 2.3a Project Area – Anderson Dam Area
Ogier Pond to Metcalf Pond ~~Lower CWMZ~~ Restoration Evaluation[1,9]	Following the construction of the Ogier Ponds CM described above, and following implementation of post-construction operations, conditions for steelhead are anticipated to improve not only in the FCWMZ, but also downstream of Ogier Ponds, potentially improving the function of the CWMZ downstream of Ogier Ponds to Coyote Creek Golf Course Drive and habitats further downstream ~~towards Metcalf Road~~. In consideration of the predicted improved rearing conditions for steelhead, a geomorphic and habitat evaluation of Coyote Creek from Ogier Ponds to Metcalf Road would be conducted to describe existing channel conditions and habitat suitability for steelhead (e.g., channel confinement, channel incision, floodplain condition, spawning gravel quality and deposition, water temperatures, flows, and passage). This evaluation would include a detailed evaluation of flows and water temperatures post-construction within the reach from Ogier Ponds to Metcalf Road. Future restoration opportunities to increase channel width, decrease pool depth, increase access to off-channel or side channel habitat, increase spawning gravel deposition and quality, and assess passage challenges for steelhead in this reach would be described. This effort would also include conceptual design opportunities in up to three key locations that could be used for future restoration projects by other programs (e.g., FAHCE).	None. This component includes an evaluation study only and does not involve construction activities.	None. This component includes development of an evaluation study that does not involve operation and maintenance activities. Implementation of any conceptualized habitat improvements identified in the evaluation study would occur as part of future adaptive management phases of the FHRP and could require additional CEQA assessment and other regulatory approvals.	None

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
Maintenance of the North Channel Reach ~~North Channel Extension~~	During and after completion of Project construction, Valley Water would continue to maintain the wetland bench, restoration plantings, and flow capacity within the North Channel Reach, directly downstream of Anderson Dam, which was restored as part of the FOCP and FOCP's HMMP. This restoration activity would include regular monitoring to ensure the integrity of reach, as needed, and the clearing of the channel if flows are compromised. More information is provided in Section 2.6.2. ~~During the FOCP, weirs were constructed at the mouth of both the North and South Channels of Coyote Creek downstream of the existing outlet structure. The construction of the weirs provides the ability for Valley Water to split outlet flows between the North and the South Channels. The weirs were designed so that flows would be split between the channels in a manner that provides environmental benefits to each channel and would not increase the existing potential for fish stranding. The restoration of the North Channel through the historic creek alignment as part of the Project would include extending the limits of the North Channel that was constructed as a part of the FOCP, by grading additional channel through County Parks and private property and reconnecting the channel to the Coyote Creek confluence with the South Channel downstream. High flows would be managed between the channels to direct larger flows through the restored North Channel, limiting flows within the South Channel. This would minimize the potential for erosion and support salmonid spawning within the South Channel, while minimizing fish stranding throughout the restored North Channel where deep holes would be graded out, and facilitate access for channel maintenance. The grading of the North Channel alignment would eliminate the existing deep pools throughout this reach that otherwise may result in fish stranding as water recedes after high flow events.~~ ~~Habitat enhancements in the restored North Channel may also include the establishment of a sediment injection point for the placement of 500 cy of sediment that would be mobilized by high flows for improving downstream substrate conditions. This action would be integrated with the long-term Sediment Augmentation Program described below. Additional restoration activities in this area would include replanting native vegetation, native landscaping, and integrating park features around the restoration areas (fences, trails, benches).~~	Maintenance for FOCP HMMP components would be implemented throughout the construction-phase of the Project to ensure that the benefits are protected from additional sediment release while Anderson Reservoir is held at a low elevation, and to account for any changes to this section of Coyote Creek that may occur during the Project. ~~Construction related to modifications of the North Channel is described in Section 2.6.2.~~	Maintenance of the wetland bench, restoration plantings, and flow capacity would include the replacement of plantings and/or materials that would be required to restore the wetland bench. In-channel work may also be required to remove accumulated sediment, debris, and vegetation if flows are impeded within the North Channel. ~~Maintenance within the North Channel would include ongoing vegetation and sediment management, as needed. This may include hand removal and/or work equipment within the channel to maintain flow capacities. Ongoing sediment placement within the North Channel would also occur to enhance salmonid habitat downstream throughout Coyote Creek in accordance with the Sediment Augmentation Program. These activities are further discussed in Section 2.9.3.~~	Figure 2-3a Project Area – Anderson Dam Area
Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach (Maintenance Activities at the Live Oak Restoration Reach)	During and after completion of Project construction, Valley Water would continue to maintain spawning gravel and rearing habitat improvements in the Live Oak Restoration Reach directly downstream of Anderson Dam, which was restored as part of the FOCP's HMMP. Maintenance of the Live Oak Restoration Reach will address the potential effects of reservoir dewatering and sediment deposition on spawning and rearing habitat from the FOCP and Project, and address ongoing operational effects of the dam post-construction~~.~~ ~~This restoration activity would include regular~~ Regular monitoring would ~~to~~ ensure the integrity of the placed woody debris; and, as needed, replacement of gravel that may have been eroded. Spawning gravel placement would be integrated with the long-term Sediment Augmentation Program, described below. More information is provided in Section 2.6.5.	Maintenance for FOCP HMMP components would be implemented throughout the construction-phase of the Project to ensure that the benefits are protected from additional sediment release while Anderson Reservoir is held at a low elevation, and to account for any changes to this section of Coyote Creek that may occur during the Project.	Maintenance of spawning gravels in the south channel would be accomplished by placing between 1 to 10 cy of gravel in the South Channel every 5 years. If high flows are not experienced in this reach, the spawning gravels may stay in place and require only minor additions. Maintenance of installed wood structures would require replacing structures and associated hardware if they appear to be creating hazardous conditions within Live Oak Park. Stop logs on the southern weir could be deployed to increase frequency of the flows through the North Channel, which could aide adaptive management of vegetation and sediment injection sites.	Figure 2-3a Project Area – Anderson Dam Area

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
Sediment Augmentation Program	To address the historical effects of course sediment loss for steelhead habitat from creek banks and bed incision below Anderson Dam, Valley Water would implement a Sediment Augmentation Program ~~during and~~ after completion of the Project. Sediment augmentation activities would improve geomorphic processes that create and maintain steelhead habitat (sediments and spawning gravels) and reduce channel incision that is typical in Lower Coyote Creek downstream of the dam. Valley Water ~~This program~~ would develop a Sediment Augmentation Plan no later than two years prior to Valley Water's planned completion ~~consist initially of removing and stockpiling approximately 55,000 cy~~ of ADSRP construction ~~suitable sediment from the exposed sources~~ in consultation with the TWG. In accordance with this plan, ~~dry Anderson Reservoir lakebed between the Dunne Avenue Bridge and the Holiday Estates boat launch staging area throughout the duration of Project construction or at an offsite source. The~~ following completion of ADSRP construction, sediment would initially be placed within the Live Oak Restoration Reach, ~~in Coyote Creek at multiple locations downstream of Anderson Dam~~ and later during adaptive management within the Live Oak Restoration Reach or ~~and~~ Ogier Ponds Restoration Reach based on locations most in need of additional sediments, as determined by construction phase sediment monitoring and deposition ~~disposition~~ monitoring. Sediment loads would be delivered by trucks and standard construction equipment. Initially, the trucks would off load approximately 500 cy of sediment starting with one site ~~at the base of the dam, near the confluence of the North and South Channels~~ within the Live Oak Restoration Reach ~~and Ogier Ponds~~. ~~This site~~ The Live Oak Restoration Reach or Ogier Ponds Restoration Reach would be replenished with up to 500 cy every 5 years based on annual monitoring results. From ~~During~~ and after completion of construction, monitoring of the Sediment Augmentation Program would occur as part of the post-construction Project and FAHCE AMP and would be reviewed by the AMT. The monitoring for this habitat restoration CM would ~~will~~ include long-term collection of sediment transport data relative to flows, and carrying out fisheries habitat and sediment deposition monitoring by collecting substrate composition and spawning and rearing habitat quality transect data throughout the CWMZ. Monitoring would also include visual inspections of low-flow trail crossings that tend to accumulate sediment to inform adaptive management and identify areas that may require in-stream maintenance such as unblocking culverts.	Construction actions related to the Sediment Augmentation Program are described in Section 2.6.3	Up to ~~Approximately~~ 500 cy of sediment would be placed in multiple locations within the Live Oak Restoration Reach or Ogier Ponds Restoration Reach every 5 years during the operational phase. Monitoring activities associated with the Sediment Augmentation Program would be part of the Post-Construction Project and FAHCE AMP.	Figure 2-3a Project Area – Anderson Dam Area
Geomorphic Flows Plan	The Geomorphic Flows Plan would identify flow releases from Anderson Dam that would be integrated into Post-Construction Operations to provide additional support for biological features of steelhead critical habitat that are maintained by periodic high flows capable of inundating the floodplain, scouring substrate, mobilizing gravel, and supporting channel migration, as described in the high flows principles of the California Environmental Flows Framework (CEFWG 2021). The Geomorphic Flows Plan would interact with the other conservation measures to achieve the following physical channel maintenance objectives downstream of Anderson Dam: mobilize substrate, scour and transport fine sediments, maintain unembedded gravel, support gravel bar formation, reduce riparian vegetation encroachment, support formation of inset benches and floodplains, increase channel migration and bank erosion, and create and maintain a wider active channel and topographic diversity.	Valley Water would start collecting the data needed and conducting the necessary analysis to work collaboratively with the TWG to develop the Geomorphic Flows Plan aimed at minimizing impacts by identifying the frequency, magnitude, and duration of Geomorphic Flow Releases necessary to achieve the physical channel maintenance objectives. Data collection and analysis may start during the Construction Phase and will continue into the Post-	The Geomorphic Flows Plan would be prepared prior to completion of construction in consultation with the TWG, and implemented post-construction and would include specific flow targets to benefit steelhead and salmon, including floodplain inundation flows, ~~and~~ spawning gravel maintenance flows, and channel forming flows. Implementation of the Geomorphic Flows Plan would occur as part of future adaptive management in consultation with the AMT pursuant to the Post Construction Project and FAHCE AMP, and could require additional CEQA assessment. Initial assumptions for the plan are as follows but would be subject to the Project and FAHCE AMP process: 1. Floodplain inundation flows would initially be >65 cfs for at least 7 days every year and will be revised based on results of inundation mapping and consultation with the	

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
		Construction Phase. ~~None~~	TWG. 2. Spawning gravel maintenance flows would initially be 250 cfs every three years for 24 hours and will be revised based on results of sediment transport modeling and consultation with the TWG. 3. Channel forming flows would initially be 1,000 cfs every seven years for 24 hours and will be revised based on results of sediment transport modeling and consultation with the TWG.	
Phase 2 Coyote Percolation Dam CM[1]	The Coyote Percolation Facility, located 11 miles downstream of Anderson Dam, is used by Valley Water to impound water for the purpose of groundwater recharge. The channel-spanning facility historically has consisted of a flashboard dam (composed of removable steel plates atop a reinforced concrete foundation), rock slope protection, fish ladder, two radial gates, and approximately 40 acres of impoundment (referred to as the Coyote Percolation Pond). As part of the FOCP, Valley Water will complete the Phase 1 improvements to this Facility, i.e., replacing the existing flashboard dam with an inflatable bladder dam to be able to accommodate high flow emergency releases following completion of ADTP. This modification will also improve the existing fish ladder by replacing existing stational fish ladder panels with adjustable panels to improve fish passage during low water level events (refer to Section 1.3.3, "*FERC Order Compliance Project*"). These improvements are referred to as the Phase 1 Coyote Percolation Dam Fish Passage Enhancements. Phase 2 Coyote Percolation Dam Fish Passage Enhancements would include the construction of a roughened channel ~~ramp~~ fishway below and up to the bladder dam to allow for improved fish passage in accordance with NMFS and CDFW fish passage criteria over the deflated bladder dam over a range of flow conditions, including necessary alterations to provide adequate flow depths and velocities across the foundation and deflated bladder dam. Studies would be developed in coordination with the TWG to understand juvenile steelhead outmigration through the Coyote Percolation Pond. These studies would focus on three key areas: predation (piscivorous, avian and aquatic species), out-migration success, and passage conditions under a variety of conditions. These studies would be developed during the Phase 2 construction period and would be implemented after Phase 2 is complete and post-construction Anderson Dam facilities operations have begun.	Construction related to the improved fishway is described in Section 2.6.4.	Consistent with current operational rules of the Coyote Percolation bladder dam, the bladder dam would be lowered only during high flow events (exceeding approximately 250 ~~320~~ cfs) and then be raised after high flow events have receded. The Coyote Percolation Dam and its appurtenances would continue to be maintained as described in the DMP. The Phase 2 Coyote Percolation Dam Fish Enhancements would be monitored post-construction (through the VAKI Riverwatcher [a computer-based fish counter] in the fish ladder and through in-stream flow/passage assessments). Routine maintenance activities associated with the passage enhancements would include removal of accumulated sediments, erosion or scour hole remediation, and vegetation removal. Maintenance staff would also inspect the roughened channel at periodic intervals, particularly after large flows, and replace roughness elements and/or repair in-channel bio-engineered habitat enhancements (e.g., rootwads, stream barbs, overhanging banks), and rock slope protection, as needed, to maintain channel function and maintain fish passage conditions. Maintenance of the Coyote Percolation Dam facility would be covered under Valley Water's DMP (2012) ~~and SMP~~.	Figure 2-3b Project Area - Coyote Percolation Dam
Coyote Creek Facilities Plan[1]	Valley Water would draft a Coyote Creek Facilities Plan that outlines strategies for the implementation of the following two primary components: **Laguna Seca Groundwater Remediation.** The plan as originally described in the FAHCE Settlement Agreement would evaluate alternatives to manage groundwater inflow from Coyote Creek. The goal is to allow flow releases from Anderson Dam to continue uninterrupted to the vicinity of Metcalf Ponds in a manner that protects other parties' properties and water rights. If a feasible alternative can be identified, Valley Water may recommend action, including design and construction schedules for implementation during FAHCE adaptive management. **Metcalf Ponds Stream Corridor Restoration.** In March 2017, Metcalf Ponds sustained damage that affects fish passage. The plan as originally described in the FAHCE Settlement Agreement would evaluate alternatives to isolate percolation ponds, quarry pits, and other	None. This component includes development of a facilities plan only and does not involve construction activities.	None. Implementation of any strategies proposed as part of the Coyote Creek Facilities Plan would occur as part of future adaptive management phases of the FHRP. Should the results of the study lead to infrastructure improvements, these improvements could require additional CEQA assessment and other regulatory approvals.	None

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
	structures from the active Coyote Creek channel in the vicinity of Metcalf Road to reestablish a free-flowing creek channel through this area. If a feasible alternative is developed, the plan may recommend action, including design and construction schedules for implementation during FAHCE adaptive management. Depending on the results of the feasibility assessments conducted for the Coyote Creek Facilities Plan as part of the Project, specific design and implementation methodologies for resultant proposed measures would be selected through the ongoing Project and FAHCE AMP implemented pursuant to the FHRP. Both components of the plan would be coordinated with the NMFS and CDFW prior to design and implementation.			
Cherry Flat Reservoir Cooperative Operating Agreement[1]	Cherry Flat Reservoir is a City of San José facility located on Upper Penitencia Creek upstream from Alum Rock Park, near the top of the watershed catchment basin. The watershed above the reservoir is 2.41 square miles of undeveloped private and publicly owned rangeland. The reservoir was built in the 1930s for flood control, water conservation, and livestock watering. This reservoir is not currently managed to support fish flows in Upper Penitencia Creek, although it is managed to maintain minimal flows through Alum Rock Park (about 0.5 cfs during summer). Presently, Valley Water has a pipeline release point into Upper Penitencia Creek that can provide spring or summer flow in this channel, when in operation. Releases into the creek are based on Valley Water operational needs for groundwater recharge, occur only after natural flows have receded upstream of the release point, and do not extend downstream to the confluence with Coyote Creek. As part of the Project and in accordance with FAHCE *Settlement Agreement* section 6.4.2.1.4 (FAHCE 2003), Valley Water would undertake reasonable best efforts to develop and execute a cooperative agreement with the City of San José regarding the operation of Cherry Flat Reservoir on Upper Penitencia Creek to ensure that habitat upstream of Valley Water facilities are kept in good condition subject to the availability of water for releases from the reservoir. In coordination with the cooperative agreement and operational plan for Cherry Flat Reservoir, Valley Water would also develop and execute an operational plan for Valley Water Facilities on Upper Penitencia Creek designed to maintain and enhance stream flow conditions for steelhead downstream of the Noble Avenue water diversion. The intent of this operational plan is to provide suitable flow conditions for adult fish passage, spawning, egg incubation, juvenile rearing, and downstream migration of steelhead in Upper Penitencia Creek.	None. Staff access could require minor maintenance of access roads and vegetation management to allow for monitoring and future activities required for adaptive management.	This Project ~~project~~ component involves development of operational plans for both City of San José and Valley Water facilities, along with monitoring and future activities for adaptive management. Implementation of an operational agreement that would occur as part of future adaptive management could require additional CEQA assessment and other regulatory approvals.	None
Payment of Santa Clara Valley Habitat Conservation Plan Impact Fees	The Project is a covered activity under the VHP (SCVHA 2012). The VHP would provide the ESA, CESA, and NCCPA compliance pathway for the Project for species under the jurisdiction of the USFWS and CDFW. Valley Water would apply for VHP coverage for Project activities and would pay impact fees for Project activities, including fees for effects on stream, wetland, riparian, and serpentine habitats under the VHA approved In Lieu Fee program. The SCVHA would then use those fees to acquire, preserve, manage, and restore populations of the covered species and the sensitive habitats that are impacted by the Project (refer to Section 3.5, *Biological Resources – Wildlife and Terrestrial Resources*). Conservation Measures would be performed in accordance with the VHP, which in some cases prescribe that the SCVHA closely match the number of individuals and quality of habitat that is acquired, preserved, and managed with the resources that are impacted. As a result, the conservation program of the VHP compensates for the Project's impacts to covered species and habitats, using	None.	None.	None

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
	the impact fees paid by Valley Water.			
Construction Monitoring				
Construction Phase Water Quality Monitoring	To minimize impacts to water quality during construction, Valley Water would conduct in-reservoir and Coyote Creek monitoring to assess water quality trends. Water quality monitoring efforts would include *Water Quality Monitoring, Sediment Deposition Monitoring, Suspended Sediment Monitoring, and Groundwater Monitoring*. More information is provided in Section 2.7.1.	None. Water quality monitoring would occur during Project construction, but would not require access improvements, vegetation management, or other construction activities.	None. No O&M activities involved with this component.	None
Construction Phase Vegetation Monitoring	Vegetation monitoring would be implemented under several approaches until completion of Project construction. Vegetation monitoring efforts would include continuation of FOCP monitoring plans, including *Phytophthora Pathogen Management Plan* (Valley Water, 2020b ~~2020f~~), *Post-Project Phytophthora Monitoring Plan (*Valley Water, 2021h*), Wetland and Riparian Habitat Dryback Monitoring* (Valley Water, 2020c ~~2020f~~*)*, and (unless and until the monarch butterfly is added to the VHP as a covered species) the *Milkweed Survey Plan* (Valley Water, 2020d). More information is provided in Section 2.7.4.	None. Vegetation monitoring would occur during Project construction, but would not require access improvements or other construction activities.	No O&M activities involved with this component.	None
Construction Phase Fisheries Monitoring	~~Fisheries monitoring identified for the FOCP and FAHCE would continue to be implemented under several approaches until completion of Project construction, as follows.~~ The fisheries monitoring efforts during construction would include ~~Fish Sampling (Valley Water 2020e),~~ Juvenile Rearing and Growth Comparative Studies (Valley Water 2023a ~~2023b~~), Environmental DNA Monitoring, ~~Fyke Trapping and PIT Tag Monitoring (Valley Water 2021c),~~ Vaki Riverwatcher Adult Escapement Monitoring, Fish Rescue and Relocation Plan ~~Surveys~~ (Valley Water 2020e ~~2020c~~), Migration Flow Monitoring, ~~Juvenile~~ Migration Study (PIT), ~~and~~ Spawning Surveys (Valley Water 2023a ~~2023b~~), spawning habitat quality and pool depth monitoring, and habitat restoration monitoring. More information on fisheries monitoring efforts is provided in Section 2.7.5.	None. Fisheries monitoring would occur during Project construction, but would not require access improvements, vegetation management, or other construction activities.	No O&M activities involved with this component.	None
Construction Phase Terrestrial Animal Monitoring	Valley Water would continue to conduct surveys for several terrestrial animal species that occur during the FOCP. Such surveys include annual surveys for nesting bald eagles (*Haliaeetus leucocephalus*) and golden eagles (*Aquila chrysaetos*), and annual monitoring surveys at a pallid bat (*Antrozous pallidus*) roost near Anderson Dam. In addition, implementation of the FOCP *Crotch's Bumble Bee Avoidance Plan* (Valley Water 2024) would continue during Project construction, as long as the species is legally protected or unless and until the Crotch's bumble bee is added to the VHP as a covered species. More information is provided in Section 2.7.7.	None. Terrestrial animal monitoring would occur during Project construction, but would not require access improvements, vegetation management, or other construction activities.	Surveys for pallid bats may occur for up to 3 years post-construction to monitor use of the Cochrane Road barn and any alternative roost structures that Valley Water may construct (if necessary). However, no O&M activities are involved with this component.	None
Construction Phase Reptile Monitoring	In coordination with USFWS, CDFW, and SCVHA, Valley Water would continue to implement western pond turtle (*Emys marmorata pallida*) monitoring efforts in suitable habitat in the FCWMZ. A Western Pond Turtle Monitoring Plan (Valley Water 2020f ~~2020h~~) was prepared for the FOCP under FERC (2020 ~~2020b~~) Order B (12). This Western Pond Turtle Monitoring Plan would be implemented as part of the Construction Phase Reptile Monitoring component. More information is provided in Section 2.7.6.	None. Reptile monitoring would occur during Project construction, but would not require access improvements, vegetation management, or other construction activities.	No O&M activities involved with this component.	None
Construction Phase Invasive Species Monitoring and Control	Valley Water prepared an Invasive Species Monitoring and Control Plan for the FOCP that would continue to be implemented through construction of the Project. The plan targets non-native fish, crayfish (*Cambaridae*), American bullfrog (*Lithobates catesbeianus*), and red-eared sliders (*Trachemys scripta*), as well as opportunistic removal of other non-native species (Valley Water, 2020g ~~2020k~~). More information is provided in Section 2.7.4.	None. Invasive species monitoring and control activities would occur during Project construction, but would not require access improvements, vegetation management, or other construction	No O&M activities involved with this component.	None

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
		activities.		
Post-Construction Operations				
FAHCE Operational Rule Curves[1]	Following Project construction, Anderson Dam facilities would be operated using the FAHCE operational rule curves developed by the Advisory Committee pursuant to the FAHCE *Settlement Agreement* (FAHCE 2003) and outlined in the Coyote Creek FHRP (Valley Water 2023a ~~2023b~~); operations would also adhere to Anderson Reservoir-specific requirements for flood management, water supply, and emergency protocols. The FAHCE rule curves describe planned releases of impounded water within Anderson Reservoir and have been developed using specific criteria with the intent to support the life-cycle needs of steelhead and Chinook salmon living in the lower Coyote Creek Watershed. Rule curve parameters identify reservoir storage levels that trigger flows releases to facilitate passage of upmigrating adult steelhead and outmigrating steelhead smolts, providing instream flows, and maintaining water temperatures suitable for juvenile rearing.	None. This component involves operational changes following construction.	Post-construction operations are described in Section 2.8.3.	Figure 2-13 Anderson-Coyote Reservoirs Combined Storage Rule Curves: FAHCE Winter Base Flows Figure 2-14 Anderson-Coyote Combined Reservoirs Operation Rule Curves: FAHCE Pulse Flows
Post-Construction Cross Valley Pipeline Extension Operation	To manage groundwater recharge and meet minimum flow targets downstream of Coyote Percolation Ponds, Valley Water would release imported water to the downstream end of the CWMZ via the Cross Valley Pipeline Extension. During post-construction operations, the Cross Valley Pipeline Extension would only be operated during dry and severely dry years when releases from Anderson Reservoir are insufficient to maintain a wetted channel to the Cross Valley Pipeline Extension outfall.[4] If stream flow from Anderson Dam does not reach the Cross Valley Pipeline Extension outfall and a dryback is present downstream, Valley Water may release imported water to Coyote Creek from the Cross Valley Pipeline Extension for managed groundwater recharge and to maintain a wetted channel downstream of the release point with no temperature limitations.	None.	During post-construction operations, the Cross Valley Pipeline Extension would only be operated in severely dry years to maintain groundwater recharge. Pipeline maintenance of the Cross Valley Pipeline Extension would be carried out as described in the PMP.	None
Phase 2 Coyote Percolation Dam and Fish Ladder Operations Plan[5]	Valley Water would develop and implement an updated operations plan for the modified Coyote Percolation Dam Facility that maximizes the benefits provided by the fish ladder and roughened approach channel improvements (i.e., Phase 2 Coyote Percolation Dam Fish Passage Enhancement), and provides for fish passage in all typical flow conditions. The updated plan would identify site access, operations to occur during the steelhead migration season (October 16 through June 14) and non-migration season (June 15 through October 15), maintenance requirements, additional details pertaining to the fish ladder, and would include other relevant documentation (e.g., Memorandum of Understanding with applicable regulatory agencies) that has been established governing the specifications and operations of facility operation.	None. This component involves development of an operations plan.	Guidance for operational activities would be developed in coordination with the TWG, and post-construction operations would be adaptively managed in consultation with the Post-Construction and Project FAHCE AMT ~~NMFS~~. Operations would involve deflation of the dam and implementation of adjustments to the fish ladder panels when flows are expected to exceed 250 ~~320~~ cfs.	None
Post-Construction Reservoir and Imported Water Storage and Releases[1]	Historic operations, which allow for storing both local and imported water in Anderson Reservoir, would continue post-Project. Typically, imported water would be put into Anderson Reservoir in late winter and spring, while the temperature of that imported water is still relatively cold, to augment local water and enable an increase in the cold-water volume in Anderson Reservoir. In addition, imported water may be put into Anderson Reservoir to augment local water at other times of the year, if necessary, to avoid losing Valley Water's water supplies stored in San Luis Reservoir or in anticipation of a planned shutdown in the conveyance system from San Luis Reservoir to Santa Clara County. Water would be added to the reservoir using the	None. This measure involves operational changes following construction.	Post-construction reservoir outflow is described in Section 2.8.2.	None

[4] Valley Water 2022a Cross Valley Pipeline Extension Post-Construction Operations Memo
[5] This plan satisfies the requirements for the Coyote Creek Facilities Plan Phase 1 measure in Accordance with Settlement Agreement Section 6.4.2.1.

Project Component	Component Description	Construction Phase	Post-Construction Phase (O&M)	Figure(s)
	multi-port outlet in a way that does not negatively impact the cold water volume available for the release to Lower Coyote Creek with the goal of maintaining/maximizing the cold water pool volume in Anderson Reservoir for discharge downstream of the FCWMZ. Finally, the new outlet works that would be constructed as part of the Project Seismic Retrofit component would enhance reservoir operations and offer flexibility for environmental benefits. Even if imported water needed to be delivered in a summer month to the upper, warmer layers of the reservoir, it would be later released to the distribution system and water treatment plants via the upper portal of the sloping intake structure and Anderson Force Main. On the other hand, releases to Lower Coyote Creek would be from the lower, cold-water pool via a 33-inch pipeline dedicated to managed recharge releases and environmental flows.			
Post-Construction Project and FAHCE AMP	Adaptive management of all post-construction operations, and all non-flow fish barrier remediation and habitat restoration conservation measures would occur in accordance with the FAHCE AMP outlined in Section 6.2 of the FHRP, which has been developed in accordance with the FAHCE *Settlement Agreement*. Pursuant to the FAHCE Framework, a project-specific Project and FAHCE AMP has been developed. The AMP includes four key elements: measurable objectives for of all post-construction operations and all non-flow fish barrier remediation and habitat restoration conservation measures, monitoring, adaptive actions if measurable objectives are not being met, and reporting. The ADSRP AMP provides measurable objectives for steelhead, trout, and salmon fisheries and their habitats. Operations and maintenance procedures and performance standards for flow and nonflow Conservation Measures identified in the AMP will contribute to the achievement of such objectives. The monitoring component would include compliance monitoring, validation monitoring, effectiveness monitoring, and long-term trend monitoring. The Project and FAHCE AMT would play an important role in adaptive management decision-making, as described in detail in the FAHCE AMP. Data and analysis would help determine whether project refinements are needed to incrementally improve instream fisheries habitat conditions. See Section 2.10 for further details.	None.	None. This component includes monitoring, reporting, and adaptive actions if measurable objectives are not being met. Should adaptive actions necessitate new or modified non-flow measures, such actions may require additional CEQA assessment and separate regulatory approvals.	None

Notes:

[1] Denotes FAHCE Phase 1 Measure that would be completed as part of the Project. Please note the following Unscreened Diversion – Upper Penitencia Creek, Singleton Road Low-flow Crossing, and the Trap and Truck Feasibility Study, have already been completed and not evaluated in the EIR. Please reference the FHRP for further information.

2.5 Seismic Retrofit Construction

Construction activities for the Seismic Retrofit components include the following: site mobilization and preparation, including clearing and preparing temporary construction access and haul roads, staging and stockpile areas; reservoir dewatering and cofferdam construction; construction of the temporary water diversion system; dam excavation and fill (including dredging, excavation of embankment materials from borrow areas and disposal of excess materials at disposal areas); construction of the new outlet works and spillway; construction other ancillary facilities; the decommissioning of the hydroelectric facility; and site restoration. Additionally, all of the Seismic Retrofit components would be constructed on bedrock foundations or on compacted fill materials that do not exhibit shrink/swell behavior.

These stages of construction are described in more detail in the sections below.

2.5.1 Construction Process and Phasing

2.5.1.1 Schedule

Construction of the Seismic Retrofit components is planned to extend over a 7-year duration. Seismic Retrofit components activities are expected to commence in the spring of Year 1 and extend through the winter of Year 7. The following bullet points provide an overview of the construction activities projected to occur by calendar year:

- Year 1: Site mobilization; full dewatering of the reservoir from deadpool to elev. 450 feet; preparation of staging areas, access and haul roads, in-reservoir stockpile areas, and borrow sites[6]; and begin tunneling for the low-level outlet works (LLOW); and acquisition of temporary construction easements (as-needed).
- Year 2: Full dewatering of the reservoir from deadpool to elev. 450 feet; cofferdam and extension pipe construction; conversion of existing Stage 1 Diversion System into Stage 2 Diversion System; dam excavation to interim dam[7] with crest of elev. 565 feet (Stage 1a Dam Excavation); and tunneling for high-level outlet works (HLOW)
- Year 3: Dam excavation to interim dam with crest El. 556 feet (Stage 1b Dam Excavation); construction of HLOW; and demolition of the existing spillway
- Year 4: Dam excavation to a remnant core (Stage 2a Dam Excavation) and dam fill to interim dam with crest elev. 556 feet (Stage 2b Fill); and construction of the spillway.
- Year 5: Dam fill to interim dam with crest elev. 565 feet (Stage 3a Dam Fill); construction of the spillway; and construction of the LLOW
- Year 6: Dam fill to new dam crest elev. 657 feet (Stage 3b Dam Fill); completion of LLOW, including sloping intake structure and outlet structure; completion of the spillway, including the unlined chute, and refilling of the reservoir
- Year 7: Permanent roadways and site restoration; and repaving Cochrane Road

[6] Since the issuance of the FERC Order, technical work reveals that the existing deadpool is actually approximately elevation 490 feet NAVD 88, and Valley Water's request to correct the FERC Order definition of deadpool is pending.

[7] During excavation of the existing dam and construction of the replacement dam there will be four winter seasons when reservoir inflows will be conveyed past the dam site through a diversion system. Inflows that exceed the capacity of the diversion system will form temporary reservoirs behind interim dams (Valley Water 2021f).

Where appropriate, construction years are referred to throughout this section to provide the reader with a general understanding for the phase at which construction would be occurring. Note that references to the “dry season” refer generally to spring and summer months when rainfall would not be expected (e.g., April 15 through October 15); references to the “wet season” refer to fall and winter months when rainfall would be expected (October 15 through April 15).[8] In general, in-channel work downstream of the dam, would occur during the dry season, but could be extended in a given year with regulatory agency approvals, contingent on weather conditions, implementation of BMPs, and remaining work activities that would need to be completed within the work season. Work within the reservoir area, including dam excavation and reconstruction, would occur in work season that extends into the “wet season” from April 1 to November 30 or later to complete work for public safety. In-channel work would occur from June 15 to October 15.

2.5.1.2 Work Hours and Crew Size

Construction activities would be conducted during a single 10-hour shift per day, between 6:00 a.m. and 4:00 p.m., Monday through Saturday, with limited Sunday work. Sunday work would include up to 12 Sundays in Years 1 through 3, up to 40 Sundays in Year 4, and up to 12 Sundays in Years 5 through 7. Specific Project ~~project~~ components that would require modified construction hours include:

- Excavation of the existing dam and construction of the replacement dam and spillway, and conversion of existing Stage 1 Diversion System into Stage 2 Diversion System – two 10-hour shifts, with a 0.5-hour lunch break (one shift between 6:00 a.m. and 4:30 p.m., and the second shift from 6:00 p.m. to 4:30 a.m., Monday through Saturday and certain Sundays
- Blasting at the Basalt Hill Borrow Area (BHBA) (described in Section 2.5.2) – restricted hours of 8:00 a.m. to 5:00 p.m.;
- Cochrane Road – communication lines and repaving – construction may occur outside the work window of 6:00 am and 4:00 pm, including weekends on a limited basis up to 24-hours a day, 6 days per week;
- Delivery of materials – 7:00 a.m. to 8:00 p.m, Monday to Friday;
- Tunneling (e.g., use of a road header) required for the outlet works (e.g., construction of the HLOW and LLOW at the dam) – up to 24 hours per day, 6 days per week; and,
- Support production (e.g., concrete placement) – 24 hours per day, 6 days per week (Valley Water 2021b ~~2021d~~)

The number of workers on site would vary based on the phase of construction. A summary of the average and maximum number of workers associated with the Project by construction phase and year is provided in **Table 2-2**.

[8] Note that dry and wet season definitions can change in consultation with regulatory agencies based on predicted weather and precipitation conditions for each year.

Table 2-2. Seismic Retrofit Workers by Construction Phase

Construction Phase	Construction Year	Daily Number of Workers (Average/Maximum)
Site Mobilization	Year 1	75/115
Stage 1a Dam Excavation	Year 2	145/180
Stage 1b Dam Excavation	Year 3	155/200
Stage 2a Excavation and Fill	Year 4	135/200
Stage 2b Excavation and Fill	Year 4	190/240
Stage 3a Dam Fill	Year 5	170/230
Stage 3b Dam Fill	Year 6	165/235
Site Restoration	Year 7	55/100

Source: AECOM 2024

2.5.1.3 Typical Equipment

The types of equipment needed for construction and durations of use would vary widely based on the Project ~~project~~ component and phase of construction. Where appropriate, typical construction equipment is discussed throughout this section to provide the reader with a general understanding of the types of construction equipment that may be used. A detailed summary of typical construction equipment required for each construction phase is provided in **Table 2-3**.

1 **Table 2-3. Seismic Retrofit Construction Sequencing and Required Construction Equipment**

Project Component	Construction Phase	Construction Activity	Approximate Duration (months)	Equipment Type
Haul and Access Roads, Stockpile and Staging Area Preparation	Year 1	Construction of the haul roads and preparation of stockpile areas	8	Bulldozers, excavators, dump trucks, water truck, motor grader, track drills
Active Treatment System (described in Section 2.5.4.2)	Years 1 to 6	Installation and operation of the water treatment system	72	3,000 gpm treatment system
Cofferdam	Year 2	Construction of the cofferdam	2	Articulated dump trucks, bulldozers, loader, long-reach excavator, track drill, crane, vibratory sheet pile driver, welder, concrete trucks, concrete pump truck, concrete vibrators, generator (80 kW)
Bypass Pump System and Extension Pipe	Years 2 to 6	Construction of the diversion extension pipe and bypass flows to Stage 2 Diversion System	60	Articulated dump truck, excavator, crane, vibratory plate, tampers, welder, generator (80 kW)
Bypass Pump System	Years 2, 6	Installation of the pumps and pipes, bypass flows to the Stage 1 Diversion System in Year 2 and to HLOW intake in Year 6	13	Three 15 cfs capacity pumps (up to two operating and one as backup), site generator (2,000 kW), truck, and loader
Dam	Stages 1a, 1b, 2a Excavation (Years 2, 3, 4)	Excavation of the existing dam (includes work at stockpile areas and reservoir disposal area)	17	Large rigid-body dump trucks, articulated dump trucks, large and medium excavators, water trucks, motor graders, bulldozers, bulldozers w/discs, rock screen for oversize materials, pumps, generator (80 kW)

Project Component	Construction Phase	Construction Activity	Approximate Duration (months)	Equipment Type
Dam	Stages 2b, 3a, 3b Fill (Years 4, 5, 6)	Construction of replacement dam (includes work at stockpile areas)	18	Large rigid-body dump trucks, articulated dump trucks, highway dump trucks, large and medium excavators, loaders, water trucks, motor graders, bulldozers, bulldozers with discs, compactors, tampers, compressors, grade-all, generator (80 kW)
Import Filter and Drain Material	Stages 2b, 3a, 3b Fill (Years 4, 5, 6)	Hauling filter and drain material to the site and stockpiling in staging area 1E	29	Highway dump trucks, bulldozer, loader
LLOW	Years 1, 2, 4, 5	Excavation of upstream portal, downstream portal, trench, and outlet structure foundation	5	Large excavator, articulated dump trucks, track drills, compressor, bobcat, shotcrete batch plant, loader, manlift, pumps, generator (80 kW)
LLOW	Year 1, 2	Tunnel and shaft excavation	2.5	Articulated dump trucks, compressors, bobcat, shotcrete batch plant, loader, manlift, pumps, ventilation fan, road-header, robotic shotcrete machine, scoop trams, generator (80 kW)
LLOW	Years 1, 2, 3, 4, 5, 6	Tunnel and shaft lining	2	Compressor, loader, manlift, crane, pumps, ventilation fan, welder, concrete trucks, concrete pump truck, concrete vibrators, generator (80 kW)
LLOW	Years 5, 6	Construction of sloping intake structure, concrete encasement, pipe supports, and outlet structure	20	Large excavator, articulated dump trucks, track drills, compressors, bobcat, loader, manlift, crane, pumps, welder, concrete trucks, concrete pump truck, concrete vibrators, generator (80 kW)

Project Component	Construction Phase	Construction Activity	Approximate Duration (months)	Equipment Type
LLOW	Year 6	Pipe, mechanical and electrical installation	12	Crane, manlift, welder, loader, generator (80 kW)
HLOW	Year 2	HLOW and access adit tunnel portal excavation	6	Large excavator, articulated dump trucks, track drills, compressors, bobcat, shotcrete batch plant, loader, manlift, generator (80 kW)
HLOW	Year 2	HLOW tunnel and access adit tunnel excavation	6.5	Articulated dump trucks, compressors, bobcat, shotcrete batch plant, loader, manlift, pumps, ventilation fan, road-header, robotic shotcrete machine, scoop trams, generator (80 kW)
HLOW	Year 2	HLOW tunnel and access adit tunnel lining	5	Compressors, loader, manlift, crane, pumps, ventilation fan, welder, concrete trucks, concrete pump truck, concrete vibrators, generator (80 kW)
HLOW	Year 3	Gate shaft excavation	2	Crane, small excavator, articulated dump trucks, track drills, compressors, shotcrete batch plant, loader, manlift, pumps, ventilation fan, robotic shotcrete machine, welder, generator (80 kW)
HLOW	Year 3	Gate shaft lining	2.5	Crane, compressors, loader, manlift, pumps, ventilation fan, welder, concrete trucks, concrete pump truck, concrete vibrators, generator (80 kW)
HLOW	Year 3	Construction of intake structure	2	Large excavator, articulated dump trucks, compressor, bobcat, loader, manlift, crane, welder, concrete trucks, concrete pump truck, concrete vibrators, generator (80 kW)

Project Component	Construction Phase	Construction Activity	Approximate Duration (months)	Equipment Type
HLOW	Year 3	Pipe, mechanical and electrical installation	3	Crane, manlift, welder, loader, generator (80 kW)
Tie-back Wall at Cochrane Road	Year 3	Construction of the tie-back wall at Cochrane Road	2.5	Medium excavator, articulated dump trucks, track drill, compressor, shotcrete batch plant, loader, manlift, generator (80 kW)
Spillway	Years 2, 3	Demolition of existing spillway	10	Excavator-mounted hoe-rams, excavators, loader, highway legal dump trucks, water trucks, compressors, jackhammers, generator (80 kW)
Spillway	Years 3, 4	Excavation and foundation preparation	15	Large and medium excavators, articulated dump trucks, highway legal dump trucks, water truck, track drills, compressors, bobcat, shotcrete batch plant, loader, pumps, generator (80 kW)
Spillway	Years 3, 4, 5	Construction of spillway structure	21	Compressors, bobcat, loader, manlift, crane, pumps, welder, concrete trucks, concrete pump truck, concrete vibrators, generator (80 kW)
Develop BHBA	Years 4, 5, and/or 6	Preparation, excavation, blasting, and hauling of material	11	Large excavators, bulldozers with rippers, articulated dump trucks, track drills, explosives truck, blasting, compressor, shotcrete batch plant, loader, manlift, generator (80 kW)
Develop Packwood Gravel Borrow Pit	Year 5	Strip sediment, excavate test trenches, excavation of borrow pit, hauling of excavated materials, and moisture conditioning	1.5	Large and medium excavators, bulldozers, articulated dump trucks, bulldozers with discs

Project Component	Construction Phase	Construction Activity	Approximate Duration (months)	Equipment Type
Main Avenue Pipeline, Anderson Force Main	Year 5	Connection of the Main Avenue Pipeline and Anderson Force Main to the LLOW outlet structure	1.5	Excavators, dump trucks, compactors, vibratory plates, tampers, welder, pumps, generator (80 kW)
Permanent Access Roads	Year 7	Restoration of parking areas, construction of permanent access roads, and repaving Cochrane Road	9	Large and medium excavators, bulldozers, articulated dump trucks, highway legal dump tracks, water truck, track drills, compressor, shotcrete batch plant, loader, manlift, motor grader, compactors, asphalt paving machine, concrete trucks, concrete pump truck, concrete vibrators, generator (80 kW)
Restoration Enhancements	Years 7 to 8	Fine grading, tree planting, construction of recreational features (~~Serpentine Bridge,~~ interpretive trail, picnic facilities, fences), revegetation/landscaping, restoration of parking areas, restoration of leach field, and bathroom remodels	12	Bobcat, watering truck, small excavator, and grader

Source: AECOM 2022

Key: cfs = cubic feet per second; gpm = gallons per minute; HLOW = high-level outlet works; kW = kilowatt; LLOW = low-level outlet works

2.5.2 Seismic Retrofit Site Mobilization and Preparation

The first year of seismic retrofit construction would primarily include mobilization and site preparation of staging areas, stockpile areas, and access roads.

2.5.2.1 Staging Areas

Designated staging areas would be used for office and equipment trailers, equipment and materials storage, equipment maintenance facilities, fuel pumps and fuel storage tanks, shotcrete batching, vehicle parking, and laydown. Portions of Anderson Lake County Park, including the Live Oak Group Picnic Area, former Toyon Group Picnic Area,[9] and boat ramp parking lots, would be used for construction staging and stockpiling. All recreational park areas located within the Project Area would be partially or fully closed to public use throughout the duration of construction.

The Project includes six staging areas: Staging Area 1, located in the Live Oak Picnic Area; Staging Area 2, located on the east sides of Cochrane Road; Staging Area 3, located in the small parking area south of the existing dam crest; Staging Area 4, located at the toe of the existing dam; Staging Area 5, located at 2100 San Pedro Avenue (approximately 2.5 miles from the Project Area); and Staging Area 6, at the Holiday Lake Estates Boat Ramp (**Figure 2-4**). Each staging area has been described below in **Table 2-4**, including the location, access, and proposed use throughout Project construction.

Staging areas would be located in upland areas. To prepare the staging areas, the construction contractor would remove vegetative groundcover and debris, grade the sites to create a flat surface for the movement of construction vehicles and equipment, and place gravel or a separation fabric over the ground surface, depending on the type of usage. Trees that are located outside of the riparian corridor but are within the staging areas would be removed. However, existing mature trees within the riparian corridor of Coyote Creek would be preserved to the greatest extent feasible.

[9] The Toyon Group Picnic Area was permanently removed as part of the FOCP.

1 **Table 2-4. Overview of Staging Areas**

Staging Area	Location	Existing Land Use	Proposed Use of During Construction	Staging Area Access and Site Preparation	Approximate Area
SA 1 (SA-1; subdivided into SA-1W and SA-1E)	North side of Cochrane Road and Coyote Creek, approximately 0.25 miles west of the dam in Anderson Lake County Park. Sub-divided into two areas: SA-1W is located south of the South Channel; SA-1E is located north of the South Channel.	Live Oak Group Picnic Area	SA-1W would be the location for contractor and construction management offices and parking for contractor supervisory staff, office staff, and construction management staff. SA-1E would be used for the storage of moisture conditioning core materials excavated during Year 2, and for the temporary stockpiling of filter and drain materials imported during Years 4, 5, and 6. A total of 120,000 cy of construction materials would be stockpiled at SA 1.	Access from Cochrane Road. SA-1W. Trees removal may be required. Existing restroom facilities would be protected in place. Water fountains may be temporarily removed for placement of office facilities. SA-1E. Access from SA-1W would require a pile supported temporary bridge across the South Channel. Preparation would include tree removal of all except those along the bank of the channel. All above ground park facilities, including water fountains and benches, would be removed. The existing maintenance bridge that crosses the South Channel would be protected in place. Approximately 1,100 linear feet of earthen berm would be constructed along the northern limits of SA-1W and approximately 2,100 linear feet of earthen berm would be constructed along the perimeter SA-1E to minimize flooding during high flow events. The earthen berms would generally measure less than 5 feet in height.	11.7 acres (SA-1W 6.5 acres, SA-1E 5.2 acres)
SA-2	SA-2 is located east of Cochrane Road at its intersection with Coyote Road	Paved parking lot and surrounding annual grassland	Construction vehicle and/or equipment parking and laydown	Access from Cochrane Road.	2.7 acres

Staging Area	Location	Existing Land Use	Proposed Use of During Construction	Staging Area Access and Site Preparation	Approximate Area
SA-3	South side of Anderson Dam, above left dam embankment. Encompasses the smaller Anderson Reservoir boat launch parking lot.	Paved parking lot	Equipment parking or laydown area	Access from SA 4 and Coyote Road. Access from SA 4 would be from an existing access road constructed during FOCP to Coyote Road. Contractor may temporarily remove lighting, landscaping, and irrigation (if not already removed during FOCP).	0.8 acre
SA-4	North side of Cochrane Road and Coyote Creek, approximately 500 feet west of the dam in Anderson Lake County Park.	Former Toyon Group Picnic Area (Note: Picnic ar ea was removed as part of FOCP)	Laydown area	Access from SA 1 and Cochrane Road. Access from SA 1 to the downstream toe of the embankment would be over a temporary dike constructed across the North Channel and through SA 4.	2.5 acres
SA-5	2100 San Pedro Avenue (approximately 2.6 miles from the Project area)	Residence and partially undeveloped	Parking area for construction workers.	Access from Hill Road. Workers would be bused from the SA 5 to the Project area. Site preparation would include fencing and placing an aggregate base surface course.	4.2 acres
SA-6	Holiday Lake Estates Boat Ramp Parking Lot	Open space and undeveloped (park closed as part of FOCP)	Equipment staging, reservoir access, and stockpiling. <u>Delivery of construction materials and equipment at Staging Area 6 would be limited to daytime hours only.</u>	Access from Holiday Drive	2.6 acres
Total Staging Areas = 6					**24.5 acres**

Source: AECOM 2022
Key: cy = cubic yards; FOCP = FERC Order Compliance Project; SA- = Staging Area

2.5.2.2 Stockpile Areas

Stockpile areas, including their locations, existing land uses, dimensional and material volume characteristics, are presented in **Table 2-5**, and are shown on **Figure 2-4**.

Designated stockpile areas would be used for temporary storage and processing of embankment and fill materials throughout the duration of construction activities. Site preparation for stockpile areas located in upland areas (e.g., Stockpile Areas B and E) would be the same as described above for staging areas, and would include clearing of vegetation and minor grading. Stockpile Area E would also require the construction of a bridge over the North Channel for access, and construction of a drainage system that would collect and convey flows around the stockpile area that would come from the unlined spillway above Stockpile Area E.

Stockpile areas would be used to store material that is either removed or extracted from the dam embankment or borrow areas. Stockpile areas located within the reservoir (e.g., Stockpile Areas C, ~~D,~~ H, I, J, K, and L) may be saturated at the time of construction; therefore, these areas may require removal and side placement of the upper layers of soft sediment to provide a stable foundation for storage of materials.

Table 2-5. Stockpile Areas

Stockpile Area[1]	Location	Existing Land Use	Approximate Area (acres)	Estimated Volume of Materials Stockpiled (cy)
Stockpile Area B	South side of Anderson Dam, above left dam embankment. Encompasses the northern portion of larger Anderson Reservoir boat launch parking lot. Overlaps portions of the BHBA.	Parking lot and open space	8	657,000
Stockpile Area C	Northern reservoir area, west-facing slope of the reservoir; opposite Packwood Gravel Borrow Pit and downstream of Stockpile Area H.	Water storage (site is inundated during normal reservoir operations)	9	425,000
Stockpile Area E	Just north of the Serpentine Trail, on the north side of Coyote Creek, roughly 800 feet west of the spillway.	Undeveloped parkland (primarily existing channel)	4	270,000

Stockpile Area[1]	Location	Existing Land Use	Approximate Area (acres)	Estimated Volume of Materials Stockpiled (cy)
Stockpile Area H	Northern reservoir area, 7,000 feet upstream from Anderson Dam, north of Stockpile Area C.	Water storage (site is inundated during normal reservoir operations)	15	689,000
Stockpile/ Borrow Area I	Northern reservoir area, upstream from Anderson Dam, north of Stockpile Area H.	Water storage (site is inundated during normal reservoir operations)	2	39,100
Stockpile/ Borrow Area J	Northern reservoir area, upstream from Anderson Dam, north of Stockpile Area I.	Water storage (site is inundated during normal reservoir operations)	7	255,000
Stockpile Area K (North and South)	Southern reservoir area, upstream from Anderson Dam, south of Stockpile Area M and the Reservoir Disposal Area.	Water storage (site is inundated during normal reservoir operations)	29	1,266,400
Stockpile Area L	Within the northern area of the reservoir.	Water storage (site is inundated during normal reservoir operations)	21	800,000
Stockpile Area M	Within the southern area of the reservoir.	Water storage (site is inundated during normal reservoir operations)	45	1,628,000
Total =			**140**	**6,029,500**

Notes:

[1] The ordering of stockpile areas is based on preliminary engineering design and some stockpile areas have been omitted due to Project design refinements (e.g., stockpile Areas A, F, and G).

Key: BHBA = Basalt Hill Borrow Area; cy = cubic yards

2.5.2.3 Access Roads

Temporary Access/Haul Roads

Primary access to the Project Area would be via US 101 and Cochrane Road. The Project Area is located east of US-101 on Cochrane Road. From Cochrane Road there would be four Project Area access points: (1) the western end of the Live Oak Picnic Area (Staging Area 1), (2) the current entrance to Toyon Park at the toe of the dam, (3) the entrance to Anderson Lake County Park (intersection of Coyote Road and Cochrane Road), and (4) North Access Point which would be from US 101 to Stockpile L as shown on **Figure 2-4**.

In order for Project personnel to access the site daily, and for the ongoing mobilization of equipment and importation of materials and supplies, the Project Area would be accessed from the western end of the Live Oak Picnic Area (Staging Area 1). Workers would park in Staging Area 5 and be bused the 2.5 miles to the Project Area (Staging Area 1) via Hill Road, East Main Avenue, and Cochrane Road. Access to Staging Area 5 for parking would be either via US 101, East Dunne Road, and Hill Road, or via US 101, Tennant Avenue, and Hill Road. The North Point Access would be from US- 101 to Metcalf Road to San Felipe Road to Las Animas Road to Stockpile L. Another alternative route to Stockpile L would be from US 101 to Silver Creek Valley to Farnswork Drive to San Felipe Road to Las Animas Road to Stockpile Area L.

Access roads and temporary bridges for construction (described further below) would be constructed within the Project Area to allow for the movement of heavy construction equipment between active work areas, staging areas, stockpile areas, borrow sites, and disposal sites. Some of the roads would be temporary and removed upon completion of construction, while others would be permanent or abandoned in-place.

Temporary access roads to be constructed would include:

- an approximately 1,100-foot-long access road along the upstream slope of the dam
- an approximately 1,200-foot-long access road on the downstream slope of the dam, connecting to an approximately 1,800-foot-long access road along the Anderson Dam Trail from the existing dam down into Staging Area 1 (Live Oak Picnic Area)
- an approximately 2,000-foot-long access road in the reservoir area to the Packwood Gravel Borrow Pit, which includes one stream crossing (riprap ford)
- an approximately 16,000-foot-long access road in the reservoir area to Stockpile Area L that would also be used to access Stockpile Area C, Stockpile Area H, Stockpile Area I, and Stockpile Area J, which includes one stream crossing (riprap ford)
- an approximately 12,000-foot-long access road in the reservoir area to Stockpile Area K that would also be used to access Stockpile Area M, which includes two stream crossings (one displacement fill with culverts and one riprap ford)

Temporary access roads for construction would be developed by the construction contractor. One-way access roads would be up to 30 feet wide with turnouts, and two-way access roads would be up to 60 feet wide with turnouts. Construction of the access roads would require minor vegetation removal and grading activities. These activities would be performed with a combination of bulldozers, excavators, dump trucks, water trucks, motor graders, track drills. Once Project construction is complete, temporary access roads located along the slope of the dam would be removed, and temporary access roads located within the reservoir area would be abandoned in-place. Temporary access roads on the downstream and upstream slope of the dam would be removed and the temporary access roads in the reservoir area connecting to the stockpile areas and Packwood Gravel Borrow Pit would be abandoned in-place.

Staging Area 1 Temporary Bridges

All temporary bridges would be constructed in a manner where all bridge abutments and supporting features are located outside of jurisdictional features, and no dredging of materials or placement of fill materials would occur within jurisdictional features including wetland or riparian habitats.

A contractor-designed, pile supported bridge, approximately 150-foot-long and 40-foot wide, would be constructed across the North Channel to provide access from the access road along the Anderson Dam Trail into Staging Area 1E. In addition, a contractor-designed, pile-supported bridge, approximately 100-feet long and 40-feet wide, would be constructed across the South Channel to provide access from Staging Area 1W to Staging Area 1E.

Cochrane Road Closure

The 0.8-mile (4,200 linear feet) section of Cochrane Road extending between Coyote Road and Malaguerra Avenue would be fully or partially closed to through traffic for varying durations throughout the construction period of 6 years. During times of roadway closure, secure access gates located at either end of the road closure would limit access to only construction-related vehicles and equipment, ~~and~~ local residents, <u>and City of Morgan Hill vehicles and emergency vehicles</u>. Barricades and/or signage would be placed at the northern terminus of St. Marks Avenue and San Rafael Street to block vehicular traffic from entering the closed area. At the southern terminus, a barricade and/or signage would be placed at Barnard Road to restrict vehicular traffic from proceeding north into the closed portion of the roadway. All vehicles, with the exception of those noted above, would be routed through a clearly marked detour using adjacent streets (Peet Road, Half Road, Elm Road, and East Main Road) to avoid the closed road. The detour would be demarcated using a combination of signage, fencing, barriers, lights, flagging, and/or guards.

The portion of Cochrane Road at the dam would require closure on three separate occasions during construction, as follows:

- An estimated 12-week period during the installation of the tie-back wall that would allow for excavation to the dam foundation level adjacent to Cochrane Road (Year 3)
- An estimated 2-week period during the tying-in of the Main Avenue Pipeline from Cochrane Road to the low-level outlet tunnel and outlet works system structure (Year 5 or Year 6)
- An estimated 4-week period during installation of communication lines from Anderson Dam to Peet Road (Year 5 or 6)
- An estimated four-week period during construction of the driveway entrance to the downstream toe of the new dam, which includes improvements to Cochrane Road on either side of the new driveway (Year 5 or Year 6)
- An estimated 10-week period for the repavement of Cochrane Road once the communication lines have been installed (Year 7).

As described above, following the completion of the construction of the Seismic Retrofit components (during Year 7), approximately 2 miles of Cochrane Road would be repaved from US 101 to the entrance to Anderson Lake County Park (intersection of Coyote Road and Cochrane Road).

2.5.2.4 Construction Materials and Sources

Materials required for the replacement of the dam embankments would originate from excavations for the original dam, the BHBA (an approximately 11.5-acre site located just south of the left dam embankment), and the Packwood Gravel Borrow Pit[10] (an approximately 14.5-acre site located on the eastern bank of the reservoir in an area that is normally inundated by the reservoir) (**Figure 2-4**). If additional materials are necessary, they would be obtained from commercial sources within the San Francisco Bay Area.

The existing embankment's core and shell materials are considered suitable for reuse; therefore, the embankment would serve as the primary source of materials for the replacement embankment. However, additional dam core and shell materials would be required. Imported materials would be used for the filter and drain zones. The transition zones are planned to be processed from existing shell materials. **Table 2-6** shows the required construction materials for the various embankment zones and cofferdam and their sources. **Table 2-7** shows the required annual number of haul trucks associated with seismic retrofit materials delivery and disposal off-haul by construction phase.

Shell and core zones of the replacement dam would be augmented with materials excavated from borrow sites. Preparation and site development activities for each borrow area are described in detail below.

Table 2-6. Summary of Seismic Retrofit Construction Materials and Sources

Material	Type	Source	Quantity Required (c y)
Upstream and Downstream Shells	Gravel with lesser amounts of sands and fines	Excavated existing shells and BHBA	2,589,300
Transition	Gravel with lesser amounts of sands and fines	Excavated existing shells	261,500
Dam core	Clay materials with gravel	Excavated existing shells and Packwood Gravel Borrow Pit	943,800
Filter and drain	Processed sand and gravel	Imported from commercial sources	456,900
Cofferdam (displaced foundation)	Unclassified excavation	Excavated diversion portal and diversion tunnel material stockpiled during FOCP and excavated in-reservoir haul road material	50,000

Source: Valley Water 2021c ~~2021e~~
Notes:
[1] Quantities are compacted in the replacement dam.
Key: BHBA = Basalt Hill Borrow Area; cy = cubic yards; FOCP = FERC Order Compliance Project

[10] If determined necessary, core materials may also originate from Stockpile/Borrow Areas I and J (refer to Section 2.5.2.).

Table 2-7. Summary of Seismic Retrofit Annual Haul Truck Trips by Construction Phase

Construction Phase	Construction Year	Rock/Aggregate/ Soil Delivery Trips[1]	Construction Materials/Supplies/ Equipment Trips[3]	Waste Disposal Off-Haul Trips[2]	Total Number of Haul Truck Trips[3]
Site Mobilization	Year 1	2,400	2,000 ~~1,400~~	100	4,500 ~~3,900~~
Stage 1a Dam Excavation	Year 2	550	2,600 ~~2,200~~	350	3,500 ~~3,100~~
Stage 1b Dam Excavation	Year 3	400	5,600 ~~5,200~~	1,500	7,500 ~~7,100~~
Stage 2a Excavation and Fill	Year 4	5,400	2,350 ~~2,100~~	100	7,850 ~~7,600~~
Stage 2b Excavation and Fill	Year 4	5,400	2,350 ~~2,100~~	100	7,850 ~~7,600~~
Stage 3a Dam Fill	Year 5	8,400	4,350 ~~3,950~~	250	13,000 ~~12,600~~
Stage 3b Dam Fill	Year 6	11,600	4,950 ~~4,550~~	350	16,900 ~~16,500~~
Site Restoration	Year 7	1,050	5,250 ~~4,650~~	200	6,500 ~~5,900~~

Source: AECOM 2022

Notes:

[1] Rock/Aggregate/Soil Delivery Trips are assumed to originate at the BHBA or Packwood Gravel Borrow Pit

[2] Off-hauling trips are assumed to go to the nearest appropriate landfill

[3] Construction Materials/Supplies/Equipment Trips (and consequently Total Haul Trips) increased as a result of further Project design refinement following release of the Draft EIR. Impacts related to these construction trip increases are reflected in this Final EIR, and no new or substantially more severe significant impacts are caused by these trip increases.

Basalt Hill Borrow Area

The BHBA, located southeast of the parking area at the left embankment of the dam(**Figure 2-4**), would provide the primary source of additional shell material for the Project. This area was previously used to construct the upstream shell of the dam in the early 1950s. The floor of the borrow area is currently occupied by a parking lot near the left abutment area of the dam.

Preparation of the BHBA would occur at the end of Year 4 and extend into Year 5, prior to the start of nesting bird season (January 15). Approximately 470,000 cubic yards (cy) of colluvium and highly weathered rock at the top of the BHBA that cannot be used for the dam embankment would be removed and disposed in the Reservoir Disposal Area (**Figure 2-4**). Topsoil (approximately 6 to 12 inches) on the west facing slope would be stripped and stockpiled in Stockpile Area B for reuse during the restoration of the Basalt Hill area. Unusable material would be excavated using a combination of bulldozers and excavators. Excavators would load off-highway haul trucks that would haul the materials to their destination. The finished slope would be faced with soil nails and shotcrete to minimize erosion.

Once usable material in the BHBA has been uncovered, the usable material would be excavated, minimally processed (to remove oversize materials[11]), and stockpiled in Stockpile Area B for use in the replacement dam (refer to Section 2.5.4) or for permanent access roads. Excavation of the BHBA would require drilling and blasting in benches to break up the rock for efficient excavation. Blasting procedures would be developed by a qualified blaster to control noise, air-overpressure, ground vibration, flyrock, and dust. Water would be used before, during, and after the blasting to minimize dust emissions.

Rock and shell material would be excavated using a combination of large excavators and bulldozers, loaded into articulated or large rigid body trucks, and hauled directly to the dam or to Stockpile Area B. Oversize rock material would be removed by bulldozers with rock rakes as the material is loaded and hauled to the dam. Oversize materials would be placed along the outer edges of the shell or disposed in the Reservoir Disposal Area. Rock bolts and shotcrete would be used to stabilize rock wedges exposed in the final slope.

Throughout the duration of Project construction, an estimated 1,677,000 ~~1,421,000~~ cy of material would be excavated from the BHBA. Of the excavated material, an estimated 1,207,000 ~~951,000~~ cy of material would be placed back in the replacement dam. The final grade would be elev. 696 (approximately 26 feet above the existing parking lot). At the final grade, the overall height of the cut slope in the BHBA would be approximately 270 feet.

Packwood Gravel Borrow Pit

The Packwood Gravel Borrow Pit would provide 160,000 ~~117,600~~ cy of additional core material for the dam, and is located within the Packwood Gravel foothills, east of Anderson Dam (**Figure 2-4).** Preparation of the Packwood Gravel Borrow Pit would begin in Year 5. Activities to prepare the site would involve the excavation of a series of test trenches using excavators. Following the test trenching, a 2- to 5-foot-thick layer of lake sediment that overlies the alluvial borrow materials (the site is within the reservoir and typically inundated) would be stripped

[11] Oversize materials in the shell are particles greater than 15 inches in size.

from the area using bulldozers. This material would be loaded into off-highway haul trucks using excavators, and then placed adjacent to the borrow area.

Once the site is ready for construction of the borrow pit area, bulldozers or excavators would begin removing material. No drilling or blasting activities would occur at this site. Excavated materials would be placed in off-highway haul trucks and spread in 1-foot-thick lifts in a stockpile adjacent to the borrow area. Each lift would be dried prior to the next lift being placed. This would involve using a bulldozer pulling a disc to a range of 2 percent below to 2 percent above the optimum moisture content. To further distribute the moisture content, the core materials would be excavated from the stockpile and hauled off-site for placement in the dam after a minimum of 30 days of curing. Materials placed in the stockpile would be used in the dam during the same dry season.

Table 2-8 provides a summary of Project borrow sites and total excavated materials.

Table 2-8. Borrow Sites

	Location	Existing Land Use	Approximate Area (acres)	Approximate Unusable Material (cy)	Approximate Usable material (cy)	Approximate Total Excavated Material (cy)
BHBA	South side of Anderson Dam, above left dam embankment. Encompasses the southern portion of larger Anderson Reservoir boat launch parking lot. Overlaps portions of the Stockpile Area B and Staging Area 2.	Parking Lot	13.6	470,000	1,207,000 ~~951,000~~	1,677,000 ~~1,421,000~~
Packwood Gravel Borrow Pit	West-facing slope of Anderson Reservoir, opposite Stockpile Area C. Site is inundated during normal reservoir operations.	Reservoir	9.0	45,000	160,000 ~~118,000~~	205,000 ~~163,000~~
Total			**26.0**	**515,000**	**1,367,000** **~~1,069,000~~**	**1,882,000** **~~1,584,000~~**

Source: Valley Water 2021c ~~2021e~~

Key: BHBA = Basalt Hill Borrow Area; cy = cubic yards

Note: Material volumes increased as a result of further Project design refinement following release of the Draft EIR. Impacts related to these material volume increases are reflected in this Final EIR, and no new or substantially more severe significant impacts are caused by these volume increases.

2.5.2.5 Reservoir Disposal Area

Materials excavated from the dam foundation, portals, tunnels, and structures, and overburden materials from borrow areas that cannot be reused onsite or at Ogier Ponds (or disposed within the borrow areas themselves) would be disposed of within the designated Reservoir Disposal Area (**Figure 2-4**). The approximately 23.4-acre disposal area is located within the reservoir on the west side of the downstream portion of the southern reservoir arm. This area supports an existing sediment layer that ranges between 10 and 15 feet in thickness (Valley Water 2021c ~~2021e~~). In the event the excavated material is not suitable for disposal in the reservoir disposal area, the material would be hauled to an appropriate landfill (such as Kirby Canyon Landfill).

Construction of the Reservoir Disposal Area would require the construction of an access road around the outer perimeter of the disposal by pushing disposal material over the existing sediment to displace it. The methodology for this construction is similar to that described for the construction of the in-reservoir cofferdam (refer to Section 2.5.4.). The first cell would be constructed during Year 2 and the second cell would be constructed during Year 3 (Valley Water 2021b ~~2021d~~). The access road, which would be constructed during Year 2, would have a crest width of approximately 60 feet and a crest of approximately elev. 470 feet, and would require approximately 270,000 cy of material for construction.

Once the perimeter road for each cell is completed, waste materials would be placed in approximately 60-foot wide strips as displacement fills along the northeast length of the access road, starting at the access road and working toward the west bank of the reservoir, to form a stable working platform across the disposal area. Any mud waves that are generated at the leading edge of each strip would be pulled back over the fill and blended in with subsequent lifts of waste fill.

Once the working platform is constructed, successive lifts of disposal material would be placed in 2-foot thicknesses across the entire area. Implementing this method, the 10 to 15 feet of lake sediment would consolidate evenly under the weight of the disposed material. The total volume of material that would be placed in Year 2 and Year 3 (this would include the materials to construct the perimeter road and would also include disposal material to complete the two cells) is estimated to be approximately 270,000 cy and 620,000 cy, respectively.

Additional disposal material excavated in Years 4, 5, and 6 would be placed evenly in 2-foot lifts across the entire Reservoir Disposal Area. Over the course of the entire Project, an estimated 1,490,000 cy of material would be placed in the disposal area. The top of the disposal area at completion of the Project would be approximately elev. 513, about 25 feet above the lowest intake port (elev. 488) and submerged during normal operations.

2.5.3 Reservoir Operations During Seismic Retrofit Construction

2.5.3.1 Anderson Reservoir Operations

Anderson Reservoir would be operated to maintain the water surface at the FERC-restricted level (i.e., deadpool until full reservoir dewatering elev. 450 feet occurs during Year 1 ~~2~~). As a part of the FOCP after the completion of the ADTP, the reservoir would be maintained at deadpool, or, if approved by FERC, a higher elevation that avoids or minimizes the risk of seismic failure of the dam and maintains the reservoir in a safe condition, while providing more water for supply and recharge.[12] If a higher elevation is approved by FERC upon completion of the ADTP, the reservoir would be brought down to deadpool elevation by the end of the year before Year 1 to allow the reservoir slopes to drain prior to the in-reservoir work activities. The operation of the reservoir at a higher elevation would also allow retention of a greater volume of imported and local water supply to facilitate groundwater recharge and emergency water storage and would allow for a deeper reservoir pool with colder temperatures, better facilitating flow releases to the FCWMZ at temperatures appropriate for steelhead.

During Project construction, and prior to the completion of the Stage 2 Diversion System, the existing 42-inch Anderson Reservoir outlet valve would be kept completely open during the wet season with a maximum flow capacity of 500 cfs (**Figure 2-6**). In addition to this, the Stage 1 Diversion ~~ADTP~~ would also be utilized, as needed, with a flow capacity up to 2,000 cfs.

The Stage 1 Diversion System would operate only until the reservoir was fully dewatered during the spring of Year 2 (**Figure 2-5**). The Stage 2 Diversion System would provide the additional flow capacity from the reservoir through the diversion system that will be required during dam removal and construction.

During the dry season of Stage 1, flows from the existing outlet structure would be between 1 to 65 ~~5~~ cfs depending on the releases from Coyote Reservoir. During the winter of Year 1 and into the wet spring season of Year 2, the reservoir levels would fluctuate depending on the releases from Coyote Reservoir and inflows from precipitation. Flows may also be released from the existing Stage 1 Diversion System to help maintain the reservoir at the restricted level. For the Stage 1 Diversion System, flows would range from as low as 1 cfs to as high as 2,500 cfs[13]. For the Stage 2 Diversion System, flows would range from 1 cfs to 65 cfs during the dry season, and up to 6,000 cfs during the wet season. These conditions would only occur in significant rain events. The Stage 2 Diversion System is designed to release a maximum of up to 6,000 cfs. For the Stage 2 Diversion System when the cofferdam is in place, flows are directed into the extension pipe during low flows throughout the construction season. During the precipitation season when high flows are likely, the extension pipe would be closed and the cofferdam overtopped so that flows would be released directly into the diversion intake structure.

The Stage 2 Diversion System is intended to operate only during embankment excavation and replacement (Year 2 through Year 6). During these years of Project construction, the Stage 2 diversion would be operable and fully open with 11-foot-diameter fixed-cone valves. Excavation of the existing dam would occur during construction seasons from Year 2 through Year 4 and replacement dam construction would occur during construction seasons from Year 4 through Year 6. The Stage 2 Diversion System would be decommissioned during Year 6; the last year of dam construction so that the LLOW can also be completed in Year 6. After the Stage 2 Diversion System is decommissioned, low flows would be pumped from upstream of the cofferdam to the HLOW, for the remainder of the Year 6 construction season. The LLOW would be used to control flows at the end of Year 6 and the remainder of Project construction.

Water resources would be managed during construction to provide groundwater recharge and incidental environmental in-stream flows throughout construction. This would allow Valley

---

[12] FERC Order Letter dated May, 2, 2023 - Existing deadpool elevation levels have been updated to be at Elevation 490.

[13]The maximum combined release capacity (2,500 cfs) includes releases through both the existing outlet works (500 cfs) and the Stage 1 Diversion System (2,000 cfs) when the reservoir level is at a spillway crest elevation of 627.9.

Water to continue to meet water supply demands in a manner that also provides fisheries habitat suitable for steelhead within the FCWMZ of Coyote Creek while Anderson Reservoir is dewatered. The design of the Project includes the following protection measures for aquatic biological resources during construction operations:

- No operational changes for Coyote Reservoir flows between Coyote and Anderson Reservoirs. Coyote Creek would remain unaltered through this reach which would benefit native aquatic plants and animals.
- All flows would be bypassed through the diversion structure throughout the winter and spring, enabling Coyote Creek downstream of Anderson Dam to experience a more natural hydrograph.
- For groundwater dewatering, all flows would be treated through the Active Treatment System (ATS) prior to release into Coyote Creek to minimize sedimentation downstream of the dam.
- All base flows from Anderson Reservoir and supplemental releases from the CDL would be released to Coyote Creek. This would include up to 10 cfs of water from the CDL that would be chilled through the chillers and released into the creek to benefit steelhead in the FCWMZ, particularly during dry weather. These flows would allow groundwater recharge and the maintenance of flows, to the greatest extent feasible, through the FCWMZ while Anderson Reservoir is dewatered.
- Supplemental imported water would be delivered into Coyote Creek through the Cross Valley Pipeline Extension downstream of Ogier Ponds, at the end of the FCWMZ. This would enable the recharge of the Coyote Valley groundwater management area and in-stream flow connectivity to the Bay throughout the construction period, while reserving releases of cooler local water bypassed from Coyote and from the CDL to support groundwater recharge and habitat conditions more suitable for steelhead within the FCWMZ.

2.5.3.2 Coyote Creek North and South Channel Operations

As described in Chapter 1, *Introduction*, there are two channels downstream of the Anderson Dam outlets: the human-made South Channel, which currently receives flows from the existing outlet works; and the re-engineered and re-established, human-made North Channel re-established pursuant to FOCP, located north of the South Channel (**Figure 2-8**). The two channels converge approximately 2,200 feet downstream of where the current outlet works discharges into the South Channel. The distribution of flows from Anderson Reservoir through the South and North Channels throughout construction of the Project and during operations of the retrofitted dam would be achieved via weirs installed at the head of each channel as a part of FOCP (Valley Water, 2023f).

The weirs and flow splits were designed to minimize the potential for erosion of the South Channel, and to maintain spawning habitat that was restored in the South Channel as part of FOCP. The expanded capacity of the North Channel that was established during FOCP provides the capacity for larger releases of water from Anderson Reservoir to be transported through Coyote Creek.

More specifically, as part of FOCP, a labyrinth weir was constructed in the North Channel. The second weir was constructed at the head of the Southern Channel that is an 8-foot-wide ‘U’ shaped channel invert weir, with slots on which stop logs can be installed. The ability to install the stop logs creates a variable weir system so that installation of the stop logs on the south weir will cause the rock-lined North Channel to be activated at reservoir releases less than 230 cfs, if needed. The restored North Channel downstream of the labyrinth weir was graded to reconnect the channel to the Coyote Creek confluence with the South Channel downstream, and to remove deep holes and pools to reduce the potential for fish stranding when flows recede. The channel was also graded to include a gradual slope toward the center of the channel to guide flows toward the deepest portion of the channel.

During ADSRP construction, ~~As part of the Project, restoration of the North Channel through the historic creek alignment would continue. The North Channel constructed as a part of FOCP would be extended by grading additional channel through County Parks and private property, and would reconnect the channel to the Coyote Creek confluence with the South Channel downstream. High~~ high flows would be managed between the channels using the labyrinth weirs to direct flows of up to 230 cfs through the South Channel, and flows greater than 230 cfs through the restored and extended North Channel, limiting flows within the South Channel. If there is a need to activate the North channel at flows lower than 230 cfs, a system of stop logs could be installed on the South Weir. This would minimize the potential for erosion and support salmonid spawning within the South Channel, while minimizing fish stranding throughout the restored North Channel where deep holes would be graded out, and facilitate access for channel maintenance. The grading of the North Channel alignment would also eliminate the existing deep pools throughout this reach that otherwise may result in fish stranding as water recedes after high flow events.

2.5.4 Construction Details and Methods for Selected Project Components

2.5.4.1 Anderson Reservoir Dewatering

While water levels within Anderson Reservoir have been substantially reduced as part of the FOCP (presently maintained at deadpool elevation, the reservoir would require full dewatering for construction of the Project. Full dewatering of the reservoir to elev. 450 feet during Year 1 would occur through the existing Stage 1 Diversion System (previously built as part of the FOCP) and continue through the Stage 2 Diversion System.

Following the same reservoir dewatering in Year 2, inflows to the reservoir would continue to be released through the Stage 1 Diversion System until the cofferdam (described in Section 2.5.4), and temporary bypass pumping system are in place (described in Section 2.5.4). During this interim period (i.e., while temporary bypass pumping system is being installed), control valves in the Stage 1 diversion system outlet structure would be left fully open, allowing inflows to be passed as they are received in the reservoir. When the cofferdam and temporary bypass pumping system are in place, inflows would be pumped to the lowest intake of the existing outlet works while conversion of the Stage 1 Diversion System to the Stage 2 Diversion System is being completed. Once completed, low flows would pass directly into the extension pipe and the Stage 2 Diversion System. During high flows, the cofferdam would be overtopped and flows would be released directly into the diversion intake structure. At this time the existing outlet works would no longer be functional and would be demolished.

2.5.4.2 Conversion of Stage 1 to Stage 2 Water Diversion

The conversion of the Stage 1 Diversion System to Stage 2 Diversion System is necessary to increase the flow capacity past the dam during Project construction. This conversion of water diversion systems from Stage 1 to Stage 2 includes constructing a cofferdam, temporary bypass pumping system, ATS, shaft, tunneling at the upstream end to connect to the Stage 1 Diversion System with a larger pipe, a temporary diversion intake structure, an extension pipe from the intake structure to upstream of the cofferdam, and abandonment of the Stage 1 Diversion System upstream of the connection to Stage 2 (**Figure 2-5 and Figure 2-6**).

Cofferdam

A cofferdam would be constructed during Year 2, located immediately upstream of the active work area at the dam to prevent releases from Coyote Reservoir and other watershed inflows from wetting the work area (**Figure 2-6**). Storage created behind the cofferdam dam would initially serve as a forebay for a bypass pumping system that would convey bypass flows to the existing outlet works, while the extension pipe and the Stage 2 Diversion System were being constructed.

The cofferdam would be constructed using stockpiled materials stored within Stockpile Area B (materials previously excavated during construction of the FOCP and materials excavated during construction of the in-reservoir roads during Year 1). Materials would be loaded into off-highway trucks using loaders or excavators, hauled to the cofferdam location, and pushed onto the sediment using bulldozers starting from the left (southeast) end of the cofferdam and advancing northwest. The sediment would be displaced, forming mud waves as the materials are pushed forward. The mud waves would likely grow large enough to necessitate the use of long-reach excavators to dredge sediments from the front and the sides of the advancing fill.

The cofferdam would have a crest length of approximately 300 feet, a crest width of 80 feet, and a crest height of elev. 465 feet. Once the cofferdam has been placed, a sheet pile cutoff wall would be constructed along the upstream crest of the cofferdam using cranes and pile driving hammers. The tops of the sheets would generally be set at elev. 450 feet. The cofferdam crest downstream of the sheet pile cutoff wall and the downstream slope of the cofferdam would be covered with rip-rap to protect the cofferdam from erosion. The total storage behind the cofferdam would be approximately 500 AF. Approximately 50,000 cy of material would be used to construct the cofferdam.

A 10-foot diameter extension pipe would be constructed from upstream of the cofferdam to the Stage 2 Diversion System intake structure. A 10-foot gate would be installed at the downstream end. At the end of the dry season, the 10-foot gate would be partially shut to allow inflows to fill the cofferdam forebay and spill onto the riprap-lined channel while also releasing flows into Coyote Creek through the Stage 2 Diversion System. Releases over the cofferdam spillway would continue until the approximately 100 AF of storage between the cofferdam and the interim embankments have filled and inflows begin to pass through the top of the Stage 2 Diversion System intake structure. With the water surfaces equalized, the 10-foot gate would be fully closed and all winter flood flows would be released through the Stage 2 Diversion System. The length of time required to equalize the water levels will depend on inflows into the reservoir area.

Temporary Bypass Pumping System

A bypass pumping system would be constructed, consisting of pumps with a capacity of 30 cfs. Approximately 950 feet of 30-inch diameter pipe would be used to convey water from the pumps to the lowest intake of the existing outlet works. The pumps would begin operating as the construction of cofferdam nears completion. The temporary bypass pumping system would be used until completion of the Stage 2 Diversion System at the end of Year 2 at which time it would be removed. The temporary bypass pumping system will be needed two additional times; during Year 3 and during Year 6. In Year 3, the temporary bypass pumping system will be needed (pumping inflows to the diversion intake structure) towards the end of the construction season to allow a 300-foot-long portion of the extension pipe to be removed to complete dam foundation excavation and backfill below the pipe. The extension pipe would be restored prior to the end of the Year 3 construction season. The temporary bypass pumping system would also be reinstalled in Year 6 (pumping inflows up to the HLOW intake structure) when the Stage 2 Diversion System is decommissioned to complete the LLOW. The volume of all flows going through the bypass system would be too great to feasibly treat them with an ATS system; therefore the bypassed flows would be directly discharged in to Coyote Creek.

Active Treatment System

To reduce turbidity and water quality impacts, localized groundwater that is pumped from the dam footprint throughout construction would be pumped from the site and routed through an ATS. The ATS would remove sediment, reduce turbidity, and balance pH from these waters prior to release into Coyote Creek, downstream of the dam. The ATS would be designed by the construction contractor based on performance requirements for a treatment flow rate of 3,000 gallons per minute (gpm), which is equivalent to 6.4 cfs. The primary treatment process in an ATS is coagulation and/or flocculation. The ATS operates through the addition of coagulant to received water. The coagulant binds to suspended sediment, causing the sediment to gravitationally settle into the bottom of the settling tanks. This sediment would then be removed from the settling tanks and hauled off site to a landfill. All materials would be tested and disposed in accordance with local, state, and federal regulations and requirements.

2.5.4.3 Temporary Diversion System

The Project includes two stages of water diversion throughout construction activities. The Stage 1 Temporary Diversion System would be converted to the Stage 2 Diversion System to continue to bypass flows in Coyote Creek behind Anderson Reservoir around the Project Area, and return flows to lower Coyote Creek throughout Project construction. The Stage 1 Diversion System would consist of a lake tap pipe with trash rack, tunnel, and an outlet structure with two 102-inch-diameter fixed cone valves and a 24-inch-diameter sleeve valve (**Figure 2-5**). The Stage 2 Diversion System would largely consist of the Stage 1 Diversion System with the exception of a screened intake structure and tunnel that would replace the lake tap pipe and trash rack of the Stage 1 Diversion System.

To convert the Stage 1 Diversion System to the Stage 2 Diversion System, the Stage 1 Diversion System would be operated until the reservoir is completely dewatered, which is expected to occur in spring of Year 1 ~~2~~ of Project construction. Once the reservoir is dewatered, construction of the Stage 2 Diversion System would begin. This conversion is expected to begin in Year 1 of

Project construction, after the reservoir is completely dewatered, and would be completed by Year 2.

Construction of the water diversion system would generally involve: excavation of the upstream diversion intake portal, excavation and support for the diversion system horseshoe tunnels (upstream portion of the low-level outlet tunnel), construction of the tunnel linings, construction of the diversion intake structure, and construction of the diversion extension pipe, including a section at the right end of the cofferdam that would be encased in concrete to allow heavy truck traffic to cross the pipe. Once the temporary diversion system is in place, the temporary bypass pumping system (described above) would be shutoff and inflows would be directed into the diversion extension pipe and through the Stage 2 Diversion System. The 350-foot-long, 8-foot-diameter steel pipe at the upstream end of the Stage 1 Diversion System would be abandoned by filling with lightweight cellular concrete.

2.5.4.4 Vegetation Clearing and Disposal

As previously described, the entire vegetated Project Area, including the proposed construction staging areas, borrow areas, stockpile areas, disposal areas, parking areas, and “off-street” access/haul roads would be cleared and grubbed. Clearing consists of the felling, trimming, and cutting of trees and removal of varying amounts of brush and other vegetation. Grubbing consists of the removal of stumps and roots below ground. During the construction and post-construction phase, beneficial reuse of trees, shrubs, and chip materials may occur throughout the site for restoration, habitat restoration, and soil stabilization purposes. Vegetation that is not suitable for reuse would be disposed off-site. Cleared vegetation would be disposed of either onsite (left-in-place or used with construction activities) or off-site (transported for various forms of approved reuse or landfill). In addition to clearing and grubbing, topsoil from the staging areas, overburden from borrow areas, and sediments from stockpile areas would be stripped. For staging and borrow areas, stripped material would be reused where appropriate (e.g., regraded over the excavated borrow areas) or disposed of in the Reservoir Disposal Area. For stockpile areas, stripped material would be placed nearby (e.g., side casted). These activities would be performed with a combination of bulldozers, excavators, and dump trucks.

2.5.4.5 Dam Excavation, Reconstruction, and Crest Raising

During Year 1, approximately 33,000 cy of sediment would be dredged from the upstream toe of the existing dam, near the existing intake structure. Dredged sediments would be placed in the reservoir ~~an extension of the in-reservoir dredge disposal area used for dredging during ADTP construction~~.

The dam replacement process would begin in the dry season (April through November) of Year 2, after the reservoir is fully dewatered and Coyote Road has been removed from the top of the dam. Likewise, as discussed in Section 2.5.1, all earth-moving activities would occur during the dry season of each construction year, with extensions only as permitted with appropriate weather conditions and permit requirements.

All but a small portion of the existing clay core would be removed and replaced through Project implementation. Reusable embankment material would be hauled to designated stockpile areas during excavation where the materials would be moisture-conditioned and disced, if needed, prior to being hauled back to the dam site for placement as part of dam reconstruction. Existing embankment materials would be augmented with material from the BHBA and Packwood Gravel Borrow Pit. The filter (sand) and drain (gravel) materials may be imported from offsite sources. Specific stages of dam excavation and reconstruction, including raising the dam crest, would be constructed, as described below.

Stage 1 Dam Excavation

The first stage of dam excavation (Stage 1a) would occur in the beginning of the dry season of Year 2. Stage 1a would involve: (1) removal of the dam crest down to elev. 565 feet; and (2) removal of the outer portion of downstream shell down to elev. 500 feet. The Stage 1a interim dam would have a crest width of approximately 150 feet and a crest length of approximately 960 feet. Excavated materials would be hauled to various stockpile areas or the Reservoir Disposal Area using up to 70 cy dump trucks.

Core materials would be wet enough that they would require drying. After excavation, core materials intended to be used later as fill would be either dried in the stockpile area prior to being covered with additional material or temporarily moved to various staging areas, where materials would be dried. The drying process would include spreading the material (with an approximated 1-foot lift) and repeatedly passing a disc pulled by a bulldozer for approximately 1 to 2 days. Materials dried in various staging areas would then be loaded onto haul trucks and relocated to stockpile areas. The total volume of material in Stage 1a Excavation is estimated to be 1,210,000 cy.

The second stage of dam excavation (Stage 1b Excavation) would occur in the dry season of Year 3. Stage 1b Excavation would involve: (1) removal of the outer portion of the upstream shell and underlying alluvium down to the valley bottom; (2) bringing the interim dam crest down to elev. 546 feet; and (3) removal of the outer portion of the downstream shell and underlying alluvium down to the valley bottom[14]. The Stage 1b interim dam would have a crest width of approximately 40 feet and a crest length of approximately 970 feet. Excavated materials would be hauled to various stockpile areas or the Reservoir Disposal Area using up to 70-cy dump trucks. Excavated alluvium would be placed in the Reservoir Disposal Area. Just prior to the wet season, a sheet pile wall would be placed across the interim dam crest to provide 10 feet of freeboard, bringing the Stage 1b interim dam crest level to elev. 556 feet. The total volume of material in Stage 1b Excavation is estimated to be 1,574,000 cy.

To complete Stage 1 Excavation, a temporary tie-back wall would be installed along a 400-foot-long segment of Cochrane Road at the toe of the dam. The tieback wall would support Cochrane Road for approximately 2 years until completion of Stage 3a Fill. The temporary tieback wall would be a soil nail and shotcrete wall, approximately 400 feet long, and 50 feet in height above the Stage 1b Excavation grade. Instrumentation, including survey monuments (physical markers), and an inclinometer, would be installed along the tieback wall alignment prior to construction for the purposes of stability monitoring. The tieback wall would be constructed in lifts, where each lift would involve excavation of a bench 2 to 4 feet below the next row of soil nails, and shotcrete the exposed excavation face. Shotcrete would be applied using a high-powered spray technique where concrete is applied from a hose to the receiving surface where

[14] The bottom of the excavation on the downstream side will be at about El. 380, 30 feet below the current valley bottom. The bottom of the excavation on the upstream side will be at about El. 400, 50-60 feet below the current valley bottom.

the material dries to form a hard surface. Tieback wall construction would require an excavator and track drills (for drilling and installing the row of soil nails) using track drills.

Stage 2 Excavation and Fill

Stage 2 includes the third, and final, stage of dam excavation (Stage 2a Excavation), to occur in the first half of the dry season of Year 4. Stage 2a Excavation would involve removal of all remaining shell material, underlying alluvium, and core down to a remnant core. The top of the remnant core would have a width of 10 feet at elev. 455 feet and a length of about 500 feet. A geomembrane would be temporarily placed and secured over the remnant core to protect it until new core material is placed against it. Excavated material would be hauled to various stockpile areas or the Reservoir Disposal Area using up to 70 cy dump trucks. Excavated alluvium would be placed in the Reservoir Disposal Area. The total volume of Stage 2a Excavation is estimated to be 899,000 cy.

Once excavation is complete, the dam fill portion of Stage 2 (Stage 2b Fill) would commence in Year 4. The inner portions of the upstream and downstream rocky earthfill shells, filter, drain, and transition materials, and the dam core, would be replaced. At the end of the construction season, the dam would have an interim elev. of 556 feet. The total volume of material in Stage 2b Fill is estimated to be 1,120,000 cy.

Stage 3 Dam Fill

The final stages of dam fill (Stages 3a Dam Fill and 3b Dam Fill) would occur over Years 5 and 6. The dam fill activities would involve placement of the remaining portions of the upstream and downstream rocky earthfill shells; the filter, drain, and transition materials; and the dam core. Shell and transition materials would come from in-reservoir stockpiles, augmented with BHBA materials. Core materials would come from in-reservoir stockpiles, materials stockpiled below the dam during Stage 1a Excavation in Year 2, and from Packwood Gravel Borrow Pit materials. The filter (sand) and drain (gravel) materials would be imported from offsite sources. At the end of Stage 3a Dam Fill, the interim dam would remain at elev. 565 feet. At the end of Stage 3b Dam Fill, and the full dam reconstruction, the dam crest would be completed at its final design of elev. 656 feet. The total volume of material in Stage 3a and Stage 3b Dam Fill is estimated to be 1,436,000 cy and 1,532,000 cy, respectively.

2.5.4.6 Interim Dam Winterization

During excavation of the existing dam and construction of the replacement dam, there would be four wet seasons when the existing spillway would not be available and reservoir inflows would be conveyed past the dam site through the Stage 2 Diversion System. Inflows that exceed the capacity of the Stage 2 Diversion System would form temporary reservoirs behind the interim dams that would be in place at the end of Stage 1a, Stage 1b, Stage 2b, and Stage 3a. The varying crests of the interim dams would be overtopped when inflows during large infrequent storm events are large enough that the Stage 2 Diversion System capacity plus interim reservoir storage capacity are exceeded. Without proactive winterization measures, overtopping could result in the potential loss of the interim dam and subsequent downstream flooding depending on the amount and duration of overtopping. To prevent loss of interim dams, an articulated concrete block-lined (ACB) spillway would be constructed on the downstream slope of the interim dams to convey safely some volume of overtopping flow past the interim dams as a winterization measure (Valley Water 2022b). Sheet pile guide walls installed along the interim dam crests would guide flows into the ACB-lined spillways. Flows from the bottom of the ACB-lined spillways would be conveyed to Coyote Creek through a gabion-lined discharge channel.

ACB-Lined Spillway Installation

The interim dam ACB-lined spillway would vary in invert width by interim dam stage with invert widths of 136 feet for Stage 1a and Stage 3a and 200 feet for Stage 1b and Stage 2b. The total lengths, including the gabion-lined discharge channel range from 900 to 930 feet. Construction of the ACB-lined spillway would occur concurrently with other earthwork on the interim dam but would not be able to be completed until the other earthwork is completed. Installation of the ACB-lined spillway would include subgrade preparation, geotextile installation, placement of a stone-filled confinement layer, installation of a geogrid layer and concrete blocks (9-inch-thick, 8-foot by 20-foot), grouting, construction of gabion mattresses and walls, and installation of sheet pile guide walls.

Access to install the ACB-lined spillway and discharge channel would be from the left abutment via temporary haul roads from Stage Area 2 and from Staging Area 1 over a dike crossing the north channel and through Staging Area 4.

At the end of each winter season, the ACB-lined spillway installed during the previous stage would be removed in reverse order so that the embankment is ready for the following construction stage. The ACBs, drainage stone, gabion stone, and sheet-pile would be salvaged during removal and placed in Staging Area 2 for reuse the following winter, to the extent possible.

2.5.4.7 Construction of Outlet Works

High-Level Outlet Works

Construction of the HLOW would occur in Years 2, 3, and 4 of construction, commencing in Year 2 only after: (1) excavation and hauling of 100,000 cy of core material to Staging Area-1E has been completed, and (2) the on-site access road between the dam and Staging Area-1E is no longer needed for dam excavation (**Figure 2-7**).

Construction of the HLOW system would consist primarily of: the downstream high-level outlet tunnel portal excavation (approximately 25,000 cy); the upstream high-level outlet tunnel and access adit tunnel (AAT) portal excavation (approximately 31,100 cy); installation of infrastructure support, including soil anchors and shotcrete of the upstream and downstream portals; construction of the high-level outlet tunnel (9,600 cy) and AAT (1,100 cy); installation of the high-level outlet tunnel and AAT linings; and construction of the HLOW intake structure.

Bulkheads would be installed at the upstream end of the high-level outlet tunnel (invert elev. 528) and the AAT (invert elev. 563) to prevent water from entering the tunnels if the reservoir level was to ever rise above the invert levels during construction. Excavation (1,300 cy), support, and installation of the final lining of the HLOW gate shaft would occur following demolition of the left training wall of the existing spillway (Section 2.5.4.). Construction would include all mechanical, electrical, and testing/commissioning work to make the HLOW operational. Excavated materials would be hauled to the Reservoir Disposal Area.

Low-Level Outlet Works

Construction of the LLOW would occur in Years 1 through 6. Construction would include the following: trench excavation to uncover the downstream end of the LLOW tunnel and to expose the outlet structure foundation (37,000 cy); removal of the existing bulkhead at the downstream end of the low-level outlet tunnel; construction of the reinforced concrete tunnel; construction of the mass concrete thrust block and low-level outlet structure foundation; construction of the low-level outlet structure; and construction of the tie-ins to the Main Avenue Pipeline and Anderson Force Main Pipeline. Construction would also include excavation of the sloping intake structure foundation (10,700 cy), construction of the sloping intake structure, construction of pipe saddles and installation of the 78-inch pipeline and 33-inch pipeline within the low-level outlet tunnel, and all mechanical, electrical, and testing/commissioning work to make the LLOW operational. Excavated materials would be hauled to the Reservoir Disposal Area.

2.5.4.8 Spillway Replacement

Spillway replacement would commence at the beginning of Year 3 and continue through Years 4 and 5. A small portion of the spillway at the downstream end of the currently unlined chute would be completed in Year 7. Initial work would involve demolition of approximately 12,500 cy of steel reinforced concrete that comprises the existing spillway structure using excavators with hoe rams or hydraulic shears. The broken-up concrete would be loaded into highway legal haul trucks and hauled to a concrete recycling facility, the nearest of which is located in San José, approximately 16 miles away. Drill and blast methods to break up concrete in the existing spillway are not proposed. Demolition of the spillway would start with removal of the left training wall structure to provide access to the top of the high-level outlet gate shaft. Demolition would generally occur from upstream to downstream, starting with the left training wall, followed by the right training wall, ogee crest structure, and spillway chute.

Once the existing spillway has been demolished, foundation excavation for the 4-foot-thick invert slab of the new spillway would commence. Excavation would again start at the upstream end and proceed towards the downstream end. Foundation excavation would include an estimated 42,000 cy to deepen the currently unlined channel. Foundation excavation would also include excavation of trenches for the drainage system under the spillway invert slab, and drilling and grouting of rock anchors. The approved excavated surface would be cleaned of all loose materials and covered with a layer of shotcrete to protect the excavated surface from degrading and help facilitate cleaning prior to concrete placement.

Following foundation preparation, the concrete replacement spillway would be constructed. Construction would commence with building a gravity wall, acting as the left training wall for the spillway, and the right abutment of the top 40 feet of the dam. Due to the limited staging area downstream of the dam, it is likely that concrete would have to be imported from commercial sources. The estimated volume of concrete that would be placed in the replacement spillway, including lining of the currently unlined channel, would be 62,000 cy. Placement of reinforcement and setting the concrete forms would be performed during daylight hours. Concrete placements are likely to occur during daylight and nighttime hours.

Spillway construction would occur starting from the upstream end and end at the downstream end. The spillway construction would be constructed in the order of building the right training wall, the ogee crest structure, and the right and left chute wall. The right and left chute wall would extend through the bend into the current unlined channel and sloped concrete paving. Improvements in the currently unlined channel would also include a 120-foot-long reinforced concrete wall at the downstream end of the left bank (immediately upstream of “the falls”) to replace the temporary repairs that were made to the breach in the downstream left bank levee that occurred during the January 1997 spill event. Construction of the wall would include building the original channel foundation at the downstream left end back up, using approximately 25 feet of mass concrete[15].

Once the spillway walls and the sloped paving are completed, the access road from Staging Area 1E along the Anderson Dam Trail to the dam would be available for the hauling of materials between Staging Area 1E and Stockpile Area E and the dam embankment. At this point, vehicular traffic offsite related to material-hauling would be reduced, and construction equipment and vehicles would utilize the access road.

2.5.4.9 Pipeline Realignments

Realigned sections of the Anderson Force Main and the Main Avenue Pipeline would be installed underground within Staging Area 4 near the downstream base of the dam using the typical cut-and-cover construction method. This method involves clearing and grading the ground surface along the alignment, excavating a trench, installing the pipe sections, welding the pipeline, and backfilling the trench with the excavated material.

2.5.4.10 Installation of Dam Controls and Instrumentation

By Year 6 of the Project, the dam would have instrumentation and controls for operation of the reservoir as well as instrumentation for monitoring dam safety specifications and reservoir levels. Controls for the LLOW sloped intake structure and HLOW gate structure would be housed in a control building located on the spillway gravity wall. The control building would be 14 feet wide, 30 feet long, and 12 feet high. Controls for the LLOW outlet structure would be located within the outlet structure. Controls for the HLOW outlet structure would be located in a control building constructed during FOCP near the HLOW outlet structure. All the controls would be interconnected to allow operation from any of the three on-site controls locations. Operational instrumentation and controls would also allow facility operators to monitor reservoir releases and levels and operate the controls remotely.

Valley Water would use the dam safety instrumentation to monitor settlement and lateral movement, reservoir elevations, pore-water pressure, and seismic response. The types and purpose of instrumentation proposed at Anderson Dam are summarized in **Table 2-9**.

[15] A portion of the wall and the mass concrete would be constructed in Year 7 after core materials have been removed from Stockpile Area E.

Table 2-9. Instrumentation for Anderson Dam

Instrument	Purpose
Piezometers	Measure pore pressure
Survey monuments	Monitor three-dimensional surface deformation
Seepage weirs	Measure seepage from the blanket drain under the dam and from the low-level outlet tunnel
Accelerographs	Measure earthquake acceleration time history
Inclinometer	Monitor deflections in the downstream dam surfaces
Automated data acquisition system	Record reservoir elevations, piezometric pore pressures, seepage flows, and inclinometer deflections

Source: AECOM 2022

Communication Lines beyond Dam Excavation

During Year 6 of the Project, communication lines from Anderson Dam to Peet Road would be replaced. This Project activity would consist of installing fiber optic lines to replace existing copper telemetry cables. The fiber optic lines are necessary to provide communication network connectivity to Anderson Dam, hydroelectric facility, and the Coyote Pumping warehouse. Construction activities for this work would include trenching, excavation, and installation of pull boxes. The fiber optic cables would be installed in an approximately 5,000 linear foot trench. This trench would be constructed using the cut-and-cover construction method. Excavation depths would be up to 15 feet. To prevent the potential for the trench to collapse, the trenches would be shored. The shoring efforts would consist of installing braces or structures to retain the walls of the trench. Pull boxes to support the wiring of the communication lines would be installed along the conduit. Equipment used for this work would include excavators, trench rollers, and compactors. Any roadway impacts would be repaved with an asphalt machine. Once the communication lines have been installed, Cochrane Road from US 101 to Anderson Dam would be repaved.

2.5.4.11 Permanent Roadway Modifications

Coyote Road up to the Boat Ramp Parking Area

As part of the Project, Coyote Road from the intersection with Cochrane Road up to the Boat Ramp Parking Area would be permanently modified to provide access to the dam crest and to the marina. The intersection of Coyote Road with Cochrane Road would be widened and relocated approximately 350 feet south to provide a safer park entrance. The park entrance would include two lanes that would divide into three boat inspection lanes and one pass through lane to reduce the potential for vehicles waiting on Cochrane Road to enter the park. Grading for the boat inspection lanes would include an up to 16-foot-high retaining wall. A new park kiosk would be constructed at the boat inspection lanes. The old entrance would also be widened and improved for use as the park exit and to provide entrance access for trucks or emergency vehicles.

Portions of Coyote Road, from the old entrance kiosk to the dam crest (approximately 1,850 lineal feet), would be widened and slightly realigned from an approximately 13-foot-wide[16] one-way road, to a 30-foot-wide, two-way road. The roadway would be slightly raised and steepened to meet the crest of the replacement dam that is 9 feet higher than the existing dam. The roadway would be widened by both cutting and filling. An approximately 550-foot-long soil nail and shotcrete retaining wall would support a portion of the cut slopes located in the approximate middle third of the road. Approximately 13,600 cy of material would be excavated from the roadway alignment, and approximately 11,400 cy of compacted fill for the road would be produced from approximately 9,000 cy of excavated material from the BHBA. The road would be paved and include concrete curbs and gutters. The existing storm drainage and sanitary sewer pipelines beneath the existing road would also be raised during construction of the new road.

Coyote Road across the Dam Crest

Once dam construction is complete, Coyote Road would be replaced with a two-lane roadway, similar to the existing road alignment. The purpose of this permanent roadway modification is to allow for Valley Water maintenance activities, restrict public vehicle access across the dam due to safety concerns, and provide pedestrian access to the Serpentine Trail via the roadway. The new permanent, paved two-lane Coyote Road to be constructed along the dam crest would be approximately 1,150 feet long and 24 feet wide. Along the segment that extends from the left (south) end of the dam to the gravity wall at the right (north) end of the dam, the road would be equipped with guard rails on either side. The new roadway would no longer be a one-way loop that crosses the dam crest. The new roadway would extend on the dam crest and with a western terminus near the spillway; the portion of the roadway along the south side of the spillway would no longer be open to public vehicles. A security gate would be located at the left side (south end) to prevent public vehicular access to the dam crest.

Coyote Road along the Spillway

Coyote Road, along the spillway, would be permanently modified to provide an access road for only maintenance activities. This 1,200-foot-long segment of Coyote Road, located along the south side of the spillway, would be a one- to two-lane, 14-to 24-foot-wide paved roadway. This road segment would start at the dam crest and end at a 104-foot-diameter paved turnaround, located approximately 200 feet downstream of the end of the concrete lined spillway chute. The west end of the turnaround would connect to an unimproved access road along the south bank of the currently unlined spillway chute.

Access from Cochrane Road to Anderson Dam Toe

Permanent roadway modification would be constructed from Cochrane Road to the toe of Anderson Dam. This permanent roadway modification would be constructed to allow maintenance access to the LLOW outlet structure and HLOW outlet structure from the lower level parking lot. Access from Cochrane Road to the Anderson Dam toe would be relocated approximately 220 feet west, to improve sight distance. The access would include a paved, two-lane, 30-foot-wide driveway used to access the low-level outlet structure parking area. A 325-

[16] Some segments of the existing road are up to 24 feet wide.

foot-long, one-lane, 20-foot-wide paved access from the west end of the parking area would be used to access the high-level outlet structure access pad. A security gate would be located at the left side (south end) to prevent public vehicular access.

In addition, the shoulder width would be widened by up to 5 feet along a 740-foot-long segment of the westbound lane of Cochrane Road, from the start of the curve (northbound) to about 300 feet west of the new driveway into the Anderson Dam toe.

Access from Coyote Road to High Level Outlet Tunnel

A new access road off Coyote Road would extend across the downstream slope of the new dam to the right abutment and downstream 350 feet to a hammerhead turnout. A 20-foot wide, gravel surfaced road provides access to the high-level outlet tunnel and drop shaft. A security gate would be located at the left side (south end) to prevent public vehicular access.

Access from Cochrane Road to Left Bank of North Channel

Cochrane Road, from the left bank of the North Channel, would be permanently modified to construct a maintenance road. The maintenance road would be used to access the North and South Channel weirs, Coyote Creek, the outlet channels, and the north channel habitat enhancement features. A 950-foot-long, 14-foot-wide paved driveway, located on the north (westbound) side of Cochrane Road would be used for maintenance access to the left bank of the North Channel. This driveway would include a crossing (bridge) of the South Channel. A security gate would be located at the left side (south end) to prevent public vehicular access.

Repaving of Cochrane Road (US 101 to Anderson Dam)

As described in the section above, Cochrane Road would be repaved from US 101 to the Anderson Dam entrance at Coyote Road. The repaving of Cochrane Road from US 101 to Anderson Dam would occur once installation of the communication lines has completed in Year 7. The purpose of the repaving of Cochrane Road is to restore the road conditions and repair damage sustained during construction. Roadway paving work would begin at the southbound exit of US 101 and continue to the dam site for a total distance of approximately 2 miles. Construction activities would include milling and hauling the existing asphalt surface, removing a layer of the aggregate base, placing new aggregate base and asphalt concrete pavement, and striping the new pavement. The work would be completed using standard roadway paving equipment, including highway-legal dump trucks, bulldozers, motor graders, compactors, milling machines, asphalt paving machines, and striping machines. The paving equipment would be transported by flatbed trailers and would be staged at designated staging areas on the dam site when not in use.

The required removal depth of the existing asphalt pavement and aggregate base would be approximately 16 inches, with 12 inches of new aggregate base and 4 inches of asphalt concrete being placed thereafter. The approximate surface area for the asphalt pavement along this segment of Cochrane Road is 560,000 square feet, requiring an aggregate base and asphalt concrete volume of approximately 20,740 cy and 6,915 cy, respectively. Assuming each dump truck can carry 10 cy of material per load, approximately 5,600 truckloads would be required to haul away the existing material and haul in the new material. This work would be completed by two crews of eight workers over a period of about 2 months. The work would be phased to minimize roadway closures by closing one side of Cochrane Road at a time and completing paving within major intersections, such as Mission View Drive and Peet Road, in accordance with the Project traffic control plan.

2.5.4.12 Temporary and Permanent Modifications to Recreational Facilities

As part of the Project, several of the recreation areas and facilities within Anderson Lake County Park would be temporarily or permanently closed. A few of these closures would be an extension of areas already closed for the current DSOD restrictions and for implementation of the FOCP. The 2017 DSOD reservoir requirements restricted water-related activities at Anderson Reservoir, which limited boating and fishing in dry years due to low water levels. As part of the FOCP, FERC required Valley Water to lower reservoir levels to deadpool. The lowered reservoir conditions would continue throughout Project construction, including the lowering of the reservoir to 450 feet throughout Construction Years 2 through 5. Although a number of temporary and permanent closures would occur within Anderson County Lake Park throughout the construction of the Project, less than a mile to the west of the Live Oak Picnic Area, the Anderson Lake County Park Visitor Center would remain open throughout Project construction. This entrance would continue to provide access to Anderson Lake County Park and local trails, including the Coyote Creek Parkway, throughout construction of the Project.

As part of the FOCP, the Anderson Dam Boat Ramp and Parking Areas, Toyon Park, Basalt Hill, parking and access to Holiday Lake Estates, and trails that lead to the dam and are located on the dam have been closed since October 2020 (Valley Water, 2020h ~~2020j~~), in addition to the existing restriction on water-related activities within the reservoir discussed above. These restrictions and closures would continue during Project construction. Additional temporary and permanent closures that would occur during Project construction are discussed below. As previously mentioned, the Anderson Lake County Park Visitor Center would remain open throughout Project construction and would continue to provide access to Anderson Lake County Park and local trails, including the Coyote Creek Parkway (**Figures 3.18a-d**).

Woodchopper's Flat Picnic Area

As part of FOCP, the Woodchopper's Flat Picnic Area and trail access to the Anderson Reservoir was closed for ADTP construction, and closure would continue throughout Project construction to ensure public safety throughout the time when the reservoir levels are below FERC restricted levels. The restricted water levels within the reservoir would expose extensive reservoir rim areas that are normally covered in water; these areas may be unstable and may result in harm if utilized by the public. Therefore, closure of the Woodchopper's Picnic Area would extend to Year 7 ~~8~~, when the reservoir would be allowed to refill; the reservoir banks would be stabilized as the reservoir rim areas exposed throughout construction would be covered in water and returned to conditions that occurred prior to the FERC water level restrictions.

Temporary Trail Closures ~~Dam Crest Trail, Cochrane Trail, Lake View Trail, Rancho Laguna Seca Trail, and Serpentine Trail~~

Throughout FOCP implementation and extending throughout the construction of the Project, ~~all~~ certain trails and public access to Anderson Dam and Reservoir would be closed for all or portions of Seismic Retrofit construction to provide public safety. Closures would include the Dam Crest Trail, Cochrane Trail, Lakeview ~~View~~ Trail, Rancho Laguna Seca Trail, Gray Pine Trail, Rosendin Trail, and the Serpentine Trail within Anderson Lake County Park. The Dam Crest Trail would be temporarily closed throughout Project construction, during which the trail would be removed and replaced. The Serpentine Trail, which connects the Live Oak Picnic Area to the dam crest, has also been closed by the FOCP and would remain closed throughout Project construction. The Cochrane Trail, Lakeview ~~View~~ Trail, and Rancho Laguna Seca Trail would also be fully closed for 3 to 4 months during the initial blasting phase of Seismic Retrofit Components construction which would occur sometime during Year 4, 5, or 6 of Project construction. Aside from the trail closures within the Project boundaries of the BHBA (Lakeview Trail), there would be no planned closures of the Rosendin Park Area before Year 4 or after Year 6 of Project construction. Cochrane Trail and Rancho Laguna Seca Trail would partially reopen after the initial blasting phase is completed. Lakeview Trail, Gray Pine Trail, and Rosendin trail and portions of Rancho Laguna Seca and Cochrane Trails would remain closed for the duration of blasting in Years 4, 5, and/or 6. ~~Project construction, and would be reopened following Project construction to connect the boat launch parking lot to the Rosendin Park Area of Anderson County Lake Park.~~

Park closure and construction activities associated with the Project would involve the installation of construction fencing around the perimeter of Rosendin Park for public safety. During closure of the park in Years 4, 5, and/or 6, there would be staff hired by the construction contractor onsite 24/7 to open all gates within the park in the event of an emergency.

Live Oak Picnic Area

The Live Oak Picnic Area has been partially closed throughout FOCP implementation to provide public safety as the ADTP is constructed nearby. Throughout the construction of the Project, the entire picnic area would be closed through~~out~~ Year 7 ~~8~~. During this time, extensive tree removal would be required to allow construction access, construction implementation, and materials storage. Park features would also be removed and/or impacted by nearby construction activities. Following Project construction, all impacted park features would be replaced on-site and in-kind (40 picnic tables, eight BBQ grills, a fee station, a pay phone, a pet waste station, a pedestrian bridge, a quarter mile walking loop, 78 regular parking spaces, five Americans with Disability Act (ADA) parking spaces, restrooms, and a group picnic area with eight tables, a large BBQ, and a food preparation table). Post-construction restoration of the Live Oak Picnic Area would also include park enhancements in the areas of the park adjacent to Coyote Creek. These would include an improved walking loop (e.g., repaved, distance markings, and signage), ~~a bridge over the North Channel providing views of the creek and connection to the Serpentine Trail,~~ an interpretive trail along Coyote Creek, relocation of the group picnic area closer to restroom and parking areas, and tree replacement planting.

Serpentine Trail

Restoration of the Live Oak Picnic Area would include the reestablishment of the Serpentine Trail, a publicly accessible recreational trail connecting the picnic area with the dam crest. The trail would essentially follow its current alignment from the Live Oak Picnic Area to the top of Anderson Dam~~, including the new span bridge crossing over the North Channel. The bridge would be approximately 140 feet long and 12 feet wide~~.

Anderson Dam Boat Ramp and Parking Area

Throughout FOCP implementation and continuing through Project Construction Year 7 ~~8~~, the Anderson Lake Boat Ramp and Parking Areas would be temporarily closed. The existing boat ramp and parking lot would be replaced and improved, in coordination with County Parks, at the end of Project construction, as these areas would be used for accessing the reservoir during construction. The boat ramp parking entrance would be improved by constructing a second entrance off of Cochrane Road, dedicated inspection area, and an electric vehicle charging area. Project construction would also remove 61 parking spaces from the crest of the dam. Depending on the volume of materials excavated at the BHBA, a restored parking area would be constructed up to 30 feet above the existing parking area, requiring the construction of ramps to access and depart from this additional parking. The reconfigured design would accommodate a greater number of longer trailer parking. A barrier, such as K-rail with fence, would be constructed up to 50 feet away from the base of the excavated slope at the perimeter of the restored parking area to provide space for rock that may fall from the slope during strong seismic shaking. Restoration of the boat ramp parking area would include grading, replacement of curb and gutter, repaving, restriping, reinstallation of lighting, planters, irrigation, revegetation, and the replacement or refurbishment of the park bathroom facility.

2.5.4.13 Decommissioning of the Hydroelectric Facility

The hydroelectric facility would be decommissioned to reduce post-construction dam operating costs. Decommissioning of the hydroelectric facility would occur in Year 1 of the Seismic Retrofit components construction. Decommissioning work would occur within the existing footprint of the hydroelectric facility (0.5 acre), including staging of equipment and worker vehicle parking. Access would be achieved via a driveway that abuts Cochrane Road.

Decommissioning construction activities would include the disassembly and removal of mechanical and electrical equipment from the site, including a transformer, a switchboard, two turbines, two generators, a hydraulic power pack, hydraulic lines, electric controls, specialty valves, large diameter pipes and fittings, meters, actuators, conduits, panels, and cabinets. The equipment removal work would be completed with the utilization of a bucket truck, boom truck, and telescopic handler. The transporting of the equipment would be done using flatbed trailers. All removed equipment would be donated, recycled, or disposed at waste facilities within a 75-mile radius of the hydroelectric facility. Decommissioning the facility would require up to 20 truck trips from the hydroelectric facility site to the reuse, recycling, and/or disposal location. No excavation, trenching, or grading would be required. Decommissioning work would be completed during typical hours (described in Section 2.5.1.) and would require a daily crew of four to six workers for a duration of 6 weeks.

2.5.5 Seismic Retrofit Construction Utilities and Services

2.5.5.1 Construction Water Supply and Stormwater Drainage

Approximately 1 cfs of water from Coyote Creek upstream of the dam would be used for construction activities, including dust control and wetting of stockpiled materials. During Year 1, the water would be obtained by pumping from the Anderson Reservoir deadpool. For most of the construction period, this water would be obtained by pumping from upstream of the cofferdam. Water during Year 7, and a backup source of water for Years 1 through 6 would be obtained from the CDL and Main Avenue Pipeline. Construction water from the CDL would be provided via an approximately 300-foot-long, 6-inch-diameter water line that would be constructed from a 30-inch polyjet vault adjacent to the hydroelectric facility to Staging Area 1E. The water line would be installed using the cut-and-cover construction method, with trenching up to a depth of 5 feet. Construction would be performed with a combination of excavators, trench rollers, and compactors. Any roadway impacts would be repaved with an asphalt paver machine. Separately, construction water from the Main Avenue pipeline would be provided via modification of an existing air relief valve located in Staging Area 2.

Stormwater accumulating in the area upstream of the dam during the rainy season would be routed into the water diversion system and released directly into Coyote Creek. Stormwater accumulating in the downstream excavation area of the dam, at spillway and outlet works construction, and at the BHBA would be collected and pumped to an ATS prior to release into Coyote Creek (Section 2.5.4.2) or used for dust control. In staging areas and stockpile areas without access to existing infrastructure, stormwater would be managed using Valley Water's BMPs, as listed in Section 2.11 and included in Appendix A, *Best Management Practices and Santa Clara Valley Habitat Plan Conditions, Avoidance and Minimization Measures, and Mitigation Measures* ~~*Incorporated in the Project*~~, and also would be managed in accordance with the Stormwater Pollution Prevention Plan (SWPPP) prepared to comply with the Construction General Permit.

2.5.5.2 Construction Power Supply

During construction, electrical power would be supplied to all of the Project facilities (except facilities at the boat ramp parking area) by Pacific Gas and Electric Company (PG&E) through an existing overhead 12.47 kilovolt (kV) power distribution line along Coyote Road via a distribution line that crosses Coyote Creek with medium-voltage power cables to a pole and distribution transformer that would be constructed by PG&E during the FOCP. As part of the Project, towards the end of the Project construction duration, the distribution line and power cables over Coyote Creek, pole, and distribution transformer would be removed by PG&E after PG&E constructs new underground power cables to a new distribution transformer at a permanent location that is closer to the LLOW outlet structure. Construction loads are estimated to be 2,300 kilovolt-amps (kVA), which would be supplied via a main service entrance rated at 277/480 Volt for a three-phase, four-wire distribution system. While this proposed electrical connection should be sufficient for Project construction power supply needs, one potential exception would be power needed for the temporary bypass pumping system in Year 2, Year 3, and Year 6, where diesel powered generators would be placed to support required pumping.

For those facilities located at the boat ramp parking area, electrical power would also be supplied by PG&E through overhead lines that connect to an existing overhead 12.47 kV power distribution line along Coyote Road. These overhead lines, however, terminate at pole mounted transformers and pad mounted service equipment located at the left end of the existing dam. During the Project, the overhead lines would be disconnected so the pole, transformers, and service equipment could be demolished for dam excavation and construction. Following completion of the dam, PG&E would install a new pole, service lines, and transformers at the left end of the dam.

In the event of a major PG&E power outage, an emergency diesel generator and associated components, including an automatic transfer switch, installed during the FOCP near the diversion outlet structure, could be operated for emergency power supply. The generator, rated at 277/480 volts for a three-phase, four-wire distribution system, was sized at 500 kVA and would be able to be continuously operated. During Project construction, the generator would be relocated to a location near the LLOW.

2.5.6 Site Restoration

As construction is completed in Years 6 and 7, temporary facilities would be removed, and all temporarily disturbed areas would be restored to their pre-construction conditions, where practicable. Initial restoration would focus on those areas that would be inundated by the reservoir during reservoir refilling, or that could be impacted during spilling of the reservoir. These areas include the reservoir stockpile areas[17], the Packwood Gravel Borrow Pit, diversion extension pipe, and Stockpile Area E. Following initial restoration, efforts would shift to the BHBA, Staging Areas 1 through 4, the access road along the former Anderson Dam Trail to Staging Area 1, restoration and enlargement of the Anderson Dam Boat Ramp parking facilities, and construction of the Serpentine Trail~~ from the Live Oak Picnic Area to the dam crest~~. Restoration would generally include revegetating areas with native species (consistent with Valley Water BMPs REVEG-1 and REVEG-2, described below) where vegetation had been removed, and repaving damaged roadways.

Site-specific restoration activities, by location, are provided below in **Table 2-10**.

Table 2-10. Site Restoration

Location	Site Restoration Activities
Stockpile Areas C, H, K, L, M, and the Reservoir Disposal Area	Grading areas for drainage. Remediation and stabilization would not be required as they would be naturally submerged overtime as the reservoir refills. For the stockpiles located outside of the reservoir, areas would be compacted and hydroseeded with a native seed mix to stabilize these areas following the completion of work.
Packwood Gravel Borrow Pit	Grading areas for drainage.
Northern Stream Crossing of South Access Road to Stockpile Areas M and K	Excavation of the central portion of the stream crossing fill and removal of culverts. Excavated material would be cast on the upstream side of the portion of the stream crossing fill to remain. The central portion of the stream crossing fill to remain would have an elevation that is 460 feet or less (28 feet or more below the lowest intake structure [elev. 492]).
Cofferdam and Diversion Extension Pipe	Removal of the cofferdam, sheet pile cutoff wall, and Diversion Extension pipe where not concrete encased. The Diversion Extension pipe trench would be backfilled and compacted. The portion of the pipe that is concrete encased would be backfilled with concrete. Sheet piles would be removed. Cofferdam fill to remain would have an elev. of 450 feet.
Stockpile Area B	Restoration of parking areas, lighting, planters, and irrigation.

[17] The access roads constructed to reach the in-reservoir stockpile areas would not be restored prior to refilling of the reservoir

Location	Site Restoration Activities
Stockpile Area E	Cleaning of core material from the rock foundation and removal of the drainage system underlying the stockpile.
BHBA	Placement of 1 to 2 feet of loose material on the benches and hydroseeding with grasses and shrubs.
Staging Area 1	Removal of the temporary bridges over the North and South Channels, removal of contractor and construction manager offices, repaving of parking areas, re-installation of County Parks facilities (e.g., water fountains, irrigation, and benches), and revegetation restoration.
Staging Area 2E	Removal of fencing, reconstruction of an entry kiosk, removal of aggregate base used for parking, regrading for drainage, repaving of the portion of Coyote Road passing through the staging area, and revegetation.
Staging Area 3	Replacement of curb and gutter, repaving, restriping, reinstallation of lighting and irrigation (if removed during construction), and revegetation.
Staging Area 4	Regrading and revegetation.
Access Road to Staging Area 1 (restoration on the right abutment to Staging Area 1)	Regrading and revegetation.
North Channel Reach ~~Restoration~~	~~Regrading and revegetation~~ Revegetation and grading as needed to maintain flows within the channel.

Key: BHBA = Basalt Hill Borrow Area

2.6 Conservation Measures Construction

2.6.1 Ogier Ponds CM

The Ogier Ponds CM would consist of separating Coyote Creek from Ogier Ponds. This Conservation Measure component would provide ecological enhancements to the channel and floodplain, improve water temperature impacts of the ponds, enhance fish migration, ~~and~~ reduce fish entrainment, and integrate public access and interpretation of natural resources and historical features (interpretive signs) within and along a portion of Coyote Creek on County Parks property.

The Ogier Ponds CM would consist of reconstructing the pre-1997 creek channel to create a geomorphically stable creek with a connected floodplain, adding habitat and biological features to the creek and floodplain. The Ogier Ponds CM would include filling Pond 1 and constructing ~~two berms to create~~ a new section of creek channel and floodplain in the area of the pre-1997 creek channel. The new section of creek channel would start at Pond 1 and connect to the pre-1997 channel alignment located west of Ponds 2, 3, 4, and 5. The length of the reconstructed channel would be approximately 6,500 linear feet of the pre-1997 channel. The Ogier Ponds CM would completely fill and remove Ponds 1 and 5 ~~Pond 1~~ and partially fill Ponds 2 and 4 ~~2 and 5~~, and construct earthen berms to separate the unfilled portions of Pond 2 ~~Ponds 2 and 5~~ from the restored channel. No changes are proposed at Ponds 3 and 6. The restored channel would include a concrete spillway that would allow high flows to flow into Pond 2 (flows above 2,000 cfs). The overflows into Pond 2 would be temporarily detained in Ponds 2, 3, and 4, which are interconnected, before being released from Pond 4 back into Coyote Creek. A drainage structure equipped with fish screens would be constructed to release flows from Pond 4 to the creek downstream of the restoration reach. ~~A fish screen culvert would be installed to spill into Coyote Creek at Pond 4.~~ The new Coyote Creek channel alignment would reconnect with the existing Coyote Creek channel west ~~downstream~~ of Pond 4. The complete filling of Ponds 1 and 5 ~~Pond 1~~ and partial filling of Ponds 2 and 4 ~~5,~~ would allow restoration of flow to the pre-1997 channel with a connected floodplain. A wetland would also be created in the onsite borrow area~~,~~ between Pond 3 and the restored channel's eastern bank ~~proposed levee, in order to fill Pond 1~~. The borrow site would be excavated to a depth that will allow groundwater to surface, creating a 4.5-acre freshwater marsh adjacent to Pond 3. The restored channel and connected floodplain would have a total width ranging from 125 to 700 feet and would be able to convey 1,485 cfs, which is the maximum Anderson Dam Tunnel release capacity.

The total width of the floodplain along the new channel would be up to 700 ~~600~~ feet. The footprint of the re-established channel and connected floodplain would total approximately 45 acres, consisting of 25 acres within the pre-1997 creek channel area and 19 acres of existing open water in Ponds 1, 2, and 5 which would be converted to low-flow creek channel and connected floodplain. The new channel would include in-stream aquatic habitat enhancements and a floodplain to promote geomorphic stability and provide high-quality aquatic and riparian habitat. Native vegetation would be planted in areas along the floodplain to create riparian habitat. Higher flows would occur only in the unlikely event that Anderson Reservoir spills. Flows of Coyote Creek exceeding the channel conveyance capacity would spill over a concrete spillway into Pond 2, be temporarily detained in Ponds 2, 3, and 4 and then drain from Pond 4 to Coyote Creek through one or more culverts equipped with fish screens. The fish screens would prevent non-native and native fish from entering Coyote Creek.

The overall footprint of the channel alignment would be approximately 60 acres, composed of 45 acres of low-flow channel and connected floodplain with 15 acres of berms, maintenance roads on the berm crest, a spillway into Pond 2, and a screened structure draining Pond 4. The Ogier Ponds CM would impact ~~convert~~ approximately 43.73 ~~19~~ acres of existing open water, ~~and~~ wetlands, and riparian habitat at Ponds 1, 2, 4, and 5 to creek channel and connected floodplain habitat. ~~About 25 acres of existing~~ Existing uplands would also be converted to channel and floodplain habitat, resulting in a net increase of approximately 12.9 ~~25~~ acres of ~~in~~ aquatic, wetland, and riparian habitat.

To provide geomorphic stability and suitable fish passage and rearing conditions, the Ogier Ponds CM would include a low-flow channel designed to convey flows of approximately 30-50 cfs, which is a flow range that would occur very often post construction ~~which is the expected typical dry season flows of Coyote Creek~~ downstream of Anderson Dam after the seismic retrofit construction is complete. This 30-50 cfs flow would support managed aquifer recharge at the downstream Coyote Percolation Pond and instream recharge at downstream portions of Coyote Creek.

The low-flow channel substrate would consist of a mixture of sands, gravels, and boulders. In areas where the existing pre-1997 channel would be restored, grading would occur to create a geomorphically stable channel with natural creek gradients. The reconstructed channel would be designed to provide water depths and velocities suitable for fish passage. Large woody debris structures and boulders would be included within the channel and floodplain to create a diversity of fish habitat and high-flow refugia, while maintaining design flow capacity. To prevent an increased risk of flooding onto adjacent properties, a concrete overflow weir would be constructed near the upstream terminus of the restored channel. For this Conservation Measure component, the spillway would flow into Pond 2 because Pond 1 would be filled and eliminated. As part of the Ogier Ponds CM, the existing at-grade road crossing the pre-1997 channel at Ogier Avenue would be removed, and the existing washed-out culvert crossing at Barnhart Avenue ~~Road~~ would not be replaced. These two road crossings are fish passage impediments and would be removed to improve fish passage conditions.

The channel and floodplain separated from the ponds would be largely located on County-owned property. However, a few areas within the pre-1997 channel are privately owned, which would require acquisition of those properties through the payment of fees or the acquisition of property in fee or an easement to construct and maintain the restored channel alignment. The Ogier Ponds CM would affect seven ~~three~~ privately owned parcels and permanent property rights would be needed for portion of these parcels: Assessor's Parcel Numbers (APN) 725-05-005, 725-05-006, 725-05-011, 725-05-014, 725-05-015, ~~and~~ 725-05-016, and 725-06-004. In addition to the permanent land rights, acquisition of a temporary construction easement or lease would be needed for the privately owned Barnhart Avenue Stockpiling Area in APN 725-05-013. ~~The total area of private property requiring permanent property right acquisition to construct the CM is the Barnhart Road staging area in APN 725-05-013.~~

The Ogier Ponds CM would not directly affect ~~result in temporary impacts to~~ the Coyote Creek Trail but would result in indirect impacts (emissions of light, noise, and dust) during the expected 3-year construction period~~, due to construction activities and material hauling across the trail, resulting in temporary closures and trail detours~~. The vast majority of construction traffic would access the Conservation Measure construction area from Monterey Highway, avoiding the need to cross the Coyote Creek Trail. ~~The Ogier Ponds CM would include installation of temporary detours and/or traffic controls for trail segments within the construction area or access routes to the work area to ensure safety of trail users and facilitate continued safe use of the trail. Trail detours would be located either along Monterey Road or east of the reclamation ponds.~~ Once the Ogier Ponds CM has been constructed, public access for pedestrian and bicycle use would be established along the top of the right bank of the levee road. The public access along the levee road would reconnect to the Coyote Creek trail, just upstream of the existing pedestrian bridge.

2.6.1.1 Construction Process and Phasing

Schedule

Construction of the Ogier Ponds CM would occur over a 3-year period, primarily during the dry season (i.e., June ~~May~~ through October). Timing for the start ~~Start~~ of construction at Ogier Ponds would rely on the acquisition of property rights and land use agreements with landowners, and would also not begin until most of ~~mostly~~ the seismic retrofit is complete due to the potential for unattenuated Coyote Creek flows during Year 1 to Year 5 of ADSRP construction. Stockpiling of fill material that would be used to construct the conservation measure may occur at the Barnhart Avenue Stockpiling Area prior to the start of this Conservation Measure construction. Construction activities for this conservation measure are expected to begin in the summer of Year 6 and end in Year 8 of the seismic retrofit construction.

In addition to the 60-acre CM footprint, staging areas that would be used to store construction equipment, supplies, and materials include the Borrow Hill Staging Area and Barnhart Avenue Stockpiling ~~Staging~~ Area. The Borrow Hill area is a 7-acre area located between Pond 3 and the pre-1997 channel. The Barnhart Avenue Stockpiling ~~Staging~~ Area is a 12-acre area located at the northeast corner of Barnhart Avenue and Monterey Road that would be used solely to stockpile fill materials. Construction of this Conservation Measure component would require dewatering of the pond ~~areas~~, diversion of creek flow around the work area, and control of groundwater to minimize expected seepage into the work areas. These activities would be implemented annually during the dry season. Upland construction activities and habitat restoration planting and seeding could ~~would~~ occur during either ~~outside of~~ the dry or wet season. Fish rescue and relocation during dewatering would be conducted, as necessary, in accordance with the Fish Rescue and Relocation Plan.

The construction schedule for activities at the Ogier Ponds CM area is outlined below by calendar year.

Year 6: Mobilize equipment to work site; install upstream and downstream cofferdams on Coyote Creek and diversion pipe to convey creek flow around construction area; install shallow wells to control groundwater seepage; install potable diesel generators to power pumps; dewater Pond 1; demolition, clearing, and grubbing of channel area; import fill from BHBA and Holiday Bench; place fill in Pond 1; and remove cofferdams at end of dry season.

Year 7: Install upstream and downstream cofferdams on Coyote Creek and diversion pipe to convey creek flow around construction area; install sheet piles to isolate fill areas in Ponds 2 and 4;~~import fill material from Holiday Lakes Estate bench,~~ place fill in Ponds 2, 4, and 5; excavate and grade channel area; construct earthen berms; ~~and~~ start construction of Pond 2 spillway, construct drainage structure ~~discharge structure,~~ and fish screens ~~culvert~~; and remove cofferdams at end of dry season.

Year 8: Complete construction of the Pond 2 spillway and~~,~~ Pond 4 drainage ~~discharge~~ structure with ~~and~~ fish screens ~~culvert~~; hydroseed/~~or~~ plant disturbed areas; ~~restoration planting~~ and construct maintenance road/~~seeding; establish~~ public access along the top of the berm on the east ~~right~~ bank of the restored channel ~~levee road~~.

Work Hours and Crew Size

Construction activities (equipment maintenance, materials delivery and off-hauling) would be conducted during a single 10- ~~12~~ hour shift per day, between the hours of 7:00 a.m. and 5:00 p.m. ~~6:00 a.m. and 6:00 p.m.~~, Monday through Friday. Equipment maintenance may occur on Saturdays, between the hours 8:00 a.m. and 5:00 p.m. No work or equipment maintenance would occur on Sundays, except for operation of pumps and electric generators to control groundwater seepage which may operate at any time on any day of the week.

An average of approximately 30 workers would be required during on-site construction activities. The maximum number of workers engaged in on-site construction activities at any one time is estimated to be 50.

Typical Equipment

The types of equipment needed for construction activities at Ogier Ponds, and the durations of the use of the required equipment, would vary based on the various construction activities. A detailed summary of typical construction equipment required for each construction activity is provided in **Table 2-11**.

Table 2-11. Ogier Ponds Construction Sequencing and Required Construction Equipment

Construction Year	Construction Activity	Approximate Duration (months)	Equipment Type
Year 6	Site mobilization	7	Excavator, loader, light trucks
Year 6	Construction of the haul roads and preparation of stockpile areas	3	Bulldozer, excavator, loader, motor grader, track drill rig, light trucks, haul trucks, water trucks and pumps for water trucks
Year 6	Construct creek bypass system	1	Loader, long-reach excavator, haul truck, light trucks, water trucks, water pump for water trucks, generator(s)
Year 6	Dewater Ponds 1, 2, and 5	3	Loader, long-reach excavator, light trucks, pumps, generator(s), Giken silent pile drivers
Year 6	Clear and grub	2	Bulldozer, long-reach excavator, loader, haul trucks, light trucks, water truck, water pump for water truck
Year 6	Fill Pond~~s~~ 1 ~~and portions of Ponds 2 and 5~~	4	Bulldozer, long-reach excavator, loader, dump trucks, light trucks, water truck, water pump for water truck, conveyor(s), soil shakers and sifters
Year 7	Excavate and sort creek materials from Holiday Lakes Estates bench excavation	4	Bulldozer, long-reach excavator, loader, haul trucks, light trucks, water truck, water pump for water truck
Year 7	Bypass channel	5	Bulldozer, motor grader, scrapers, long-reach excavator, tamping foot roller, dump trucks, light trucks, water truck, water pump for water truck

Construction Year	Construction Activity	Approximate Duration (months)	Equipment Type
Year 7	Berms including filling Pond 5, and partially filling Ponds 2 and 4	5	Bulldozer, motor grader, long-reach excavator, tamping foot roller, dump trucks, light trucks, water truck, water pump for water truck
Year 7	Spillway	2	Concrete pump truck, compressor, bobcat, loader, manlift, crane (150 ton), pump, welder, concrete vibrator, light trucks, generator
Year 7	Outlet culverts	2	Concrete pump truck, compressor, bobcat, loader, manlift, crane (150 ton), pump, welder, concrete vibrator, light trucks, generator
Year 8	Spillway	1	Concrete pump truck, compressor, bobcat, loader, manlift, crane (150 ton), pump, welder, concrete vibrator, light trucks, generator
Year 8	Outlet culverts	1	Concrete pump truck, compressor, bobcat, loader, manlift, crane (150 ton), pump, welder, concrete vibrator, light trucks, generator
Year 8	Restoration planting	5	Bobcat, loader, light trucks
Year 8	Miscellaneous activities and demobilization	8	Excavator, loader, light trucks

Source: AECOM 2022

2.6.1.2 Site Mobilization and Site Preparation

During the first few months of Year 6, construction activities at Ogier Ponds would include mobilization of equipment, supplies, and materials to the staging areas and preparation of the staging area, stockpile areas, and access roads. Construction of this Conservation Measure components would require clearing of vegetation from up to 60 acres within the channel footprint and an additional 7 acres and 12 ~~19~~ acres at the Borrow Hill Staging Area and Barnhart Avenue Stockpiling Areas, respectively ~~Road Staging Area.~~ Temporary access roads would be located along areas near the rerouted channel, expanded floodplain, berms, spillway and drainage structure. Primary construction ~~Construction~~ access would be from the west via Monterey Highway, Barnhart Avenue ~~Road~~, and Ogier Avenue. It is possible a small number of construction vehicles would access the site ~~or~~ from the east via US 101, Coyote Creek Golf Course Road and unnamed roads within the County Parkland, but this route would be secondary and would receive only minimal use throughout the construction of the Conservation Measure.

Staging Areas

As mentioned above, implementation of the Ogier Ponds CM would require one ~~two~~ staging and one stockpiling area. Construction ~~areas. The two~~ staging would occur at ~~areas are~~ the 7-acre Borrow Hill Staging Area and stockpiling of fill materials would occur at the Barnhart Avenue Stockpiling ~~Staging~~ Area (~~**Figure 2-4**~~ **Figure 2-11**). The staging area~~s~~ would be used for offices and equipment trailers, equipment and materials storage, equipment maintenance facilities, fuel pumps and fuel storage tanks, construction vehicle parking, and Project ~~project~~ laydown. The Borrow Hill Staging Area is located ~~a 7-acre area~~ between the pre-1997 creek and Pond 3. This area is located in the upland areas outside the ponds and pre-1997 creek channel. The area was previously disturbed by mining use and is currently covered with sparse grasses and forbs ~~grassy vegetation~~. The Barnhart Avenue Stockpiling ~~Staging~~ Area is a 12-acre area located at the northeast corner of Barnhart Avenue and Monterey Road. The existing condition of this staging area is a fallow agricultural field. Similar to the Borrow Hill Staging Area, the Barnhart Avenue Stockpiling ~~Staging~~ Area is currently sparsely vegetated with grasses and forbs.

To prepare the two staging areas, the construction contractor would remove vegetative groundcover and debris, grade the site, as needed, to create a flat surface for the movement of construction vehicles and equipment, and place gravel or a separation fabric over portions of the ground surface, depending on usage. Following construction, the ~~The two~~ staging area and stockpiling sites would be restored to pre-Project ~~project~~ conditions.

Access

Construction equipment and vehicles, worker’s vehicles, and supply trucks would access the construction staging area and construction site via a series of existing paved and unpaved public roadways and access routes. The construction site and staging area are accessible from Monterey Highway, which runs north-south approximately 1,000 feet west of Ogier Ponds. Monterey Highway is a divided paved road with two traffic lanes in each direction. Ogier Road and Barnhart Avenue (two-lane paved roads) each provide access from Monterey Highway to Ogier Ponds. Monterey Highway, Ogier Road, and Barnhart Avenue are public roads maintained by the Santa Clara County Department of Airports and Roads. Although primary construction-period access ~~Access~~ would be from the west via Monterey Highway, a small number of construction vehicles may access the construction area from the east via ~~also occur from~~ US 101, a divided limit access freeway, Coyote Creek Golf Course Drive, a paved two-lane public road, and unnamed internal roads within the Coyote Creek Parkway which are surfaced with aggregate and have limited access due to locked gates. A network of rural roads surfaced with crushed rock would be installed at the staging and construction areas to allow internal vehicle and equipment movement throughout the Ogier Ponds area. Material hauling from BHBA would be from Cochrane Road to Monterey Road, and from Monterey Road to Barnhart Avenue. These roadways would provide access to the construction staging area from the paved public roads.

Construction Materials and Sources

Materials required for the Ogier Ponds CM would originate from excavations at the BHBA adjacent to Anderson Dam (**Figure 2-4**), on-site borrow areas, and commercial sources within the San Francisco Bay Area. **Table 2-12** shows the annual number of haul trucks associated with Ogier Ponds materials delivery and disposal off-haul by construction phase. For fill placement, the CM would require approximately 135,700 ~~210,000~~ cy ~~cubic yards (CY)~~ to be excavated onsite and 494,300 ~~420,000~~ cy ~~CY~~ to imported on-site. Total on-site excavation would be about 135,700 ~~210,000~~ cy ~~CY~~. Approximately 494,300 ~~420,000~~ cy ~~CY~~ of fill would also be trucked in from the BHBA, Borrow Hill, and/or Barnhart Avenue Stockpiling Area ~~Holiday Lakes Estates Bench~~ for use in berm creation, completely filling Ponds 1 and 5, and partially filling Ponds 2 and 4. A total of approximately 630,000 cy ~~CY~~ of material would be used to fill the ponds and construct a separation berm.

2.6.1.3 Construction Methods

The proposed channel alignment and floodplain would require clearing and grubbing prior to the start of construction activities. This would include the removal of vegetation, debris, and soils to allow for a clear construction area. Clearing and grubbing would be performed with a crew using chainsaws and a bulldozer. This material would be hauled away and disposed of at a nearby offsite landfill with adequate capacity (e.g., Kirby landfill), or chipped and reused onsite or offsite for mulch. Depending on soil testing, approximately 28 acres of surface area and approximately 135,700 ~~207,000~~ cy of material would be cut and reused on site if determined to be suitable. Adequately sized tree trunks and root wads that would maintain their composition while in creek flows (e.g., oaks, redwoods) would be retained and used for large woody debris structures in the reestablished creek channel.

The Ogier Ponds CM would include the complete filling of Ponds 1 and 5, partial filling of Ponds 2 and 4 ~~5~~, construction of earthen berms, construction of an overflow weir and drainage structure, and implementation of restoration plantings. The overflow weir would allow high creek flows to overflow into Pond 2. The drainage structure would consist of one or more culverts equipped with ~~planting. A~~ fish screens ~~screen culvert would be~~ installed at Pond 4 to allow high flows to re-enter the creek after being temporarily detained in Ponds 2, 3 and 4. No changes are being proposed at Ponds 3 and 6 for this Conservation Measures component. As mentioned above ~~in the site preparation section~~, construction of the Conservation Measures would require site preparation of approximately 60-acres of land for the planned creek reroute and creation of connected floodplain and berms. Construction activities such as clearing and grubbing, excavation, grading, hauling, dewatering, pouring concrete, installation of fish screens, and vegetation plantings would be conducted to construct the Ogier Ponds CM. Dewatering would consist of using cofferdams and/or sheet piles to hydraulically isolate the portion of ponds and or creek reach from upstream and downstream wetted areas. A series of pumps would be installed to remove water from the isolated area and discharge the water to the downstream creek. If required by high groundwater in the area causing seepage into the work area, shallow groundwater wells may be installed and operated to lower the local groundwater table. Additionally, one or more temporary pipes would be installed to convey Coyote Creek flows around the construction area and maintain flow in Coyote Creek downstream of the construction area.

Dewatering Methods

Dewatering of the Coyote Creek channel and ~~adjoining~~ portions of Ogier Ponds where construction would occur would be necessary during the dry season construction period. As mentioned above, Pond 1 and 5 would be completely filled and removed and Ponds 2 and 4 partially dewatered to enable the Conservation Measure construction. Dewatering activities would also divert creek flows around the construction area and discharge the diverted flows back to Coyote Creek to maintain flow in downstream creek reaches. ~~As mentioned above,~~

~~Ponds 1, 2, and 5 would be completely dewatered. Dewatering activities would occur in short reaches upstream and downstream of construction locations along the new channel. Temporary dewatering would be implemented sequentially from the upstream 30 construction boundary to the downstream boundary for up to 200 linear feet at each dewatering location.~~

Construction ~~Temporary methods to dewater the creek channel and portions~~ of the dewatering system ~~ponds during construction~~ would include the use of cofferdams, sheet piles, sump pumps, and/or groundwater extraction wells. Earthen cofferdams would be constructed at the upstream and downstream boundaries of the new creek channel section that would be under construction. Water would be bypassed from a location upstream of the upper cofferdam to either Pond 2 (which drains to Coyote Creek through Pond 4) ~~a location in the nearest pond,~~ or directly~~, if closer,~~ to the ~~a location~~ downstream creek channel ~~of the lower cofferdam~~ via pumps and a temporary dewatering pipe that would be placed on the surface at top of bank. The cofferdams would be constructed of on-site excavated material that is covered with a waterproof liner. Dewatering pumps and a diversion pipe would be placed to draw water from within the creek, then run along top of bank areas to an in-water release location ~~below the lower cofferdam~~ to dewater the channel and maintain dry conditions for the duration of construction ~~within each 200-foot section~~. Surface water would be piped back into the creek channel below the lower cofferdam (if downstream of the work areas), or into the nearby ponds and discharged back into the creek channel at the existing Pond 4 outlet ~~at the~~ downstream ~~terminus~~ of the construction area. Once the construction of ~~or~~ the restored ~~dewatered~~ channel is complete, the cofferdams would be removed. Construction activities would also require hauling activities to bring equipment and materials on-site and off-site. Clean materials would be hauled to the site and solid waste material would be hauled offsite. ~~Construction would require large amounts of earth movement and fill placement.~~

The construction of the Ogier Ponds CM requires the operations of approximately five diesel-powered generators and five 6-inch pumps to support dewatering and construction activities. Ponds 1 and 5 ~~, 2, and 5~~ would be completely dewatered to facilitate placement of fill and portions of Ponds 2 and 4 would be isolated using sheet piles and the isolated area dewatered. ~~This would~~ Dewatering activities would require the installation of ~~sheet piles and~~ cofferdams and possibly sheet piles to isolate Ponds 1, 2, 4, and 5 ~~the ponds~~ from Coyote Creek and the construction area, placement of water intakes in the ponds attached to pumps powered by diesel generators, and installation of shallow groundwater wells attached to pumps. The pumps would operate continuously throughout the construction period to remove existing water ~~nuisance waters~~ from the ponds and ~~would also~~ control groundwater seepage into the dewatered area. All water~~s~~ pumped from the site would be released downstream of the work area into Coyote Creek. Ongoing water quality monitoring would ensure that dewatering releases into the creek would not violate Basin Plan water quality parameters. This would provide a dry working environment for the construction of the berms and infrastructure. Once the work area is dewatered, fill material would be placed in Ponds 1, 2, 4, and 5 ~~the ponds~~, a ~~screened~~ concrete overflow structure would be constructed discharging into ~~in~~ Pond 2, and a screened concrete drainage structure would be constructed to release water from ~~in~~ Pond 4 back to Coyote Creek. Fish relocation and rescue would be conducted in areas to be dewatered prior to draining them. To install the overflow structures and fish screens, concrete setting and pouring activities would be required. Restoration planting efforts would entail soil preparation, native species planting, vegetation establishment activities, installation of bio-engineered slope protection, and placement of root wads and channel materials. Demobilization and removal of equipment and excess materials would be conducted once construction activities are completed.

Table 2-12. Summary of Ogier Ponds Annual Haul Truck Trips by Construction Activity

Construction Year	Construction Activity	Rock/Aggregate/ Soil Delivery	Waste Disposal Off Haul Trips	Total Number of One-Way Haul Truck Trips (based on 16 ~~10~~ cy truck capacity)
Year 6	Site mobilization	N/A	0	100
	Control of water	N/A	0	100
	Demolition and clear and grub	N/A	100	0
	Pond 1 Fill - Borrow Hill excavation	101,400 cy of imported soil	0	12,675 ~~20,280~~
	Pond 1 Fill Import - Basalt Hill excavation	252,200 cy of imported soil	0	31,526 ~~50,440~~
	Import and sort Creek Materials from Holiday Lakes Estates Bench Excavation	140,700 cy of imported soil	0	17,588
Year 7	~~Import and sort Creek Materials from Holiday Lakes Estates Bench Excavation~~	~~140,700 cy of imported soil~~	~~0~~	~~14,070~~
	Bypass channel	N/A	0	0
	Berms	N/A	0	0
	Spillway	N/A	0	0
	Outlet culverts	N/A	0	0
Year 8	Spillway	N/A	0	0
	Outlet culverts	N/A	0	0
	Restoration Planting	N/A	0	0

All trips represent one-way trips to the Ogier Ponds site.
Key: cy = cubic yards

Earth Movement

Ogier Ponds CM activities would require excavating about 135,700 ~~210,000~~ cy of soil from the existing ground along the restored pre-1997 channel alignment for reuse in the partial filling of ponds and construction of berms separating the creek channel from the remaining ponds. Total excavation would be about 135,700 ~~210,000~~ cy. Approximately 494,300 ~~420,000~~ cy of fill would also be trucked in from the BHBA, Quarries, and/or Holiday Lakes Estate Bench for use in filling Pond 1.

2.6.2 Maintenance of the North Channel Reach ~~Extension~~

During FOCP implementation, weirs were constructed at the division of the North and South Channels of Coyote Creek downstream of the existing Anderson Dam outlet structure. As part of the FOCP ~~Project~~, the historic North Channel of Coyote Creek was ~~would be~~ restored so that ADTP flows can be split between the North and South Channels. The weirs were designed so that low flows would be split between the channels in a manner that would provide environmental benefits to each channel by supporting continuous flows through each channel, to the greatest extent practicable, and would not increase the existing potential for fish strandings as the historic North Channel, as part of the FOCP, is being ~~would be~~ graded to extend further downstream to a confluence with South Channel to avoid the potential for a backwater to develop, and to remove existing holes and pools that may strand fish when waters recede. High flows would be split to minimize the potential for erosion of the South Channel that would be enhanced by FOCP implementation with woody debris and gravel benches to support salmonid spawning and rearing habitat and would also provide refugia for salmonids.

As part of the Project, the North Channel Reach would be maintained. Maintenance activities would include maintaining the constructed wetland bench, maintaining design flow capacity through the North Channel, and replacing restoration plantings, as needed. Some additional restoration and revegetation of the North Channel may be needed during the Project due to impacts from ongoing construction, such as construction-related high flow reservoir release. Native trees and vegetation would be planted as necessary during the Project along the banks of the channel to support effective revegetation of the channel. There are no recreational amenities planned for the North Channel area; all recreation features are planned for the banks of the South Channel (e.g., picnic areas, benches, interpretative areas, trails).

~~As part of the Project, the North Channel would be graded so that it extends through County Parks and private property to connect with the confluence of the North and South Channels of Coyote Creeks, where the existing North Channel currently forms a backwater. Currently the North Channel does not support topography that supports flows through this area. With positive drainage from the North Channel to the confluence, the restored North Channel would be designed to facilitate drainage. Grading would also channel flows towards the center of the North Channel so that flows would continue to the greatest extent feasible during low-flow times. This change in grading and flows would reduce fish stranding and stabilize both banks to protect Santa Clara County property. The north channel weir design includes a labyrinth weir that would activate the rock-lined north channel when releases from the reservoir exceed approximately 230 cfs. The weir at the head of the southern channel will include a 5-ft-wide 'U' shaped channel invert weir, with slots on which stop logs can be installed. The ability to install the stop logs would create a variable weir system so that when they are installed on the south weir, the north channel would be activated when reservoir releases exceed 100 cfs, rather than 230 cfs. The north channel downstream of the north weir would be graded to reduce fish stranding when flows recede. This would include a slight slope towards the center of the channel and a slight, approximately 1% slope towards ADTP project limits (towards Coyote Creek). Upstream of the north weir, within a perennial backwater, a wetland bench would be~~

~~installed to create suitable habitat for wetland vegetation. Riparian planting along some margins of the northern channel would be installed.~~

~~Through the restoration of the North Channel, trees and vegetation would be removed from the perimeter of the channel. Following the restoration of the North Channel, native trees and vegetation would be planted along the banks of the channel to support revegetation along the channel. There are no recreational amenities planned for the North Channel area; all recreation features are planned for the banks of the South Channel (e.g., picnic areas, benches, interpretative areas, trails). During Year 8 of the project, a new pedestrian bridge would be constructed across the North Channel. The pedestrian bridge would be constructed over the North Channel to reconnect the Serpentine Trail Equipment used to construct the new pedestrian bridge include loaders, excavators, cranes, compactors, dump trucks, and water trucks.~~

~~*2.6.2.1 Construction Process and Phasing*~~

~~Schedule~~

~~Construction activities associated with the North Channel Extension would occur during the dry season of Construction Year 1. In order to implement the North Channel work, a cofferdam would be built at the lower limit of the backwater to ensure that the backwater does not enter the work area. Additional pumps would also be placed throughout the work area to pump out nuisance waters as the groundwater levels are near the surface within the work area. The grading of the North Channel would be implemented during one dry season, and the work would occur over the course of approximately four months. Additional native vegetation would be planted during Year 7 to enhance the restored North Channel as restoration of the Project Area undertaken. A pedestrian bridge would be constructed over the North Channel during Year 8.~~

~~Work Hours and Crew Size~~

~~Generally, construction activities would be conducted during a single 12-hour shift per day, between 6:00 a.m. and 6:00 p.m., Monday through Friday. Equipment maintenance would occur on Saturdays, and no work would occur on Sundays.~~

~~An average of approximately 10 workers would be required during on-site construction activities. The maximum number of workers engaged in on-site construction activities at any one time is estimated at 20. For construction of the pedestrian bridge, work would require a daily crew of 20 to 40 workers for a duration of 3 months.~~

~~Typical Equipment~~

~~The types of equipment needed for construction and durations of use would vary based on the construction activity. A detailed summary of typical construction equipment required for each construction activity is provided in **Table 2-13**.~~

~~Table 2-13. Types of Construction Equipment – North Channel Extension~~

~~Construction Year~~	~~Construction Activity~~	~~Approximate Duration (months)~~	~~Equipment Type~~
~~Year 1~~	~~Grading~~	~~2~~	~~Bulldozer, motor grader, excavator, loader, dump trucks, light trucks, water truck, water pump for water truck~~
~~Year 7~~	~~Habitat Enhancements~~	~~2~~	~~Bobcat, loader, light trucks, water truck, water pump for water truck~~
~~Year 8~~	~~Pedestrian Bridge~~	~~3~~	~~loaders, excavators, cranes, compactors, dump trucks, and water trucks~~

~~Source: AECOM 2022~~

~~*2.6.2.2 Site Mobilization and Preparation*~~

~~Staging Areas and Access~~

~~The equipment and materials that would be required to access and for the construction of the North Channel extension would be located within Staging Area 1, the Live Oak Picnic Area.~~

~~Construction Materials and Sources~~

~~This activity would involve grading using existing materials. No additional sources would be needed.~~

~~*2.6.2.3 Construction Methods*~~

~~Construction would include clearing/grubbing; channel excavation and grading, operation of diesel-powered generators and pumps; planting of native species and vegetation establishment activities; and demobilization and removal of equipment and excess materials after construction is complete.~~

~~Dewatering~~

~~While the North Channel area is likely to be dry during the dry season work window, it is possible that a small backwater area at the downstream end of the historic North Channel of Coyote Creek may require dewatering to grade the extension of the North Channel. This would include the construction of a cofferdam, the use of pumps to dewater the work area, and groundwater extraction wells to remove nuisance waters from the work area. The cofferdam would be constructed from large gravel bags (super sacks) that are covered with waterproof liners. Dewatering pumps would be placed within the backwater to dewater the work area and maintain dry conditions for the duration of construction. Once the construction of the extended North Channel is complete, the cofferdam would be removed, and the North Channel would be reconnected along the historic alignment.~~

~~**Clearing and Grubbing**~~

~~The North Channel and access areas would require clearing and grubbing prior to construction, which includes the removal of vegetation, debris, and soils to allow for a clear construction site. Clearing and grubbing would be performed with a crew using chainsaws and a bulldozer. This material would be hauled away and disposed of, or chipped and reused onsite for mulch. Adequately sized trees that would maintain their composition while in creek flows (e.g., oak trees, redwood trees) would be retained on site and used for large woody debris structures in the reestablished creek channel. All vegetated areas would be restored to a vegetated condition in Year 7.~~

2.6.3 Sediment Augmentation Program

Sediment augmentation activities would improve geomorphic processes that create and maintain steelhead habitat (sediments and spawning gravels) and reduce channel incision that is typical in Lower Coyote Creek downstream of the dam. ~~This program would consist of removing and stockpiling approximately 55,000 cy of suitable sediment from the exposed reservoir bottom between the Dunne Avenue Bridge and the Holiday Estates boat launch (Staging Area 6, **Figure 2-4**) throughout the duration of Project construction. Sediment used from an onsite source would be washed and sorted prior to placing it in Coyote Creek. Short-term material stockpiling would occur at the creek injection site within Staging Area 1, Staging Area 6, or within an Ogier Ponds Staging Area (**Figure 2-4**).~~

Valley Water would develop a Sediment Augmentation Program no later than two years prior to Valley Water's planned completion of ADSRP construction, in consultation with the TWG. Valley Water would place sediment materials in Coyote Creek in the Live Oak Restoration Reach and/or the Ogier Ponds Restoration Reach, beginning with the Live Oak Restoration Reach, in collaboration with the TWG and using available monitoring data from the Live Oak Restoration Reach Project gravel augmentation program. At a minimum, Valley Water would ensure the Sediment Augmentation Program initially includes approximately 500 cy of sediment (composition to be determined with the TWG) placed within the Live Oak Restoration Reach following completion of ADSRP construction, including the Ogier Ponds CM and initiation of Anderson Dam post-construction operations. Annual sediment deposition and transport monitoring and long term habitat assessment monitoring would be conducted as a part of this Conservation Measure, and sediment in this reach would be replaced in an amount up to 500 cy as necessary to replenish sediment at least every 5 years. If high flow events mobilize all the injected sediment within the Live Oak Restoration Reach, additional sediment would be added during the 5 year period to replenish the volume of sediment placed. All additional sediment augmentation would occur within the Live Oak Restoration Reach and within the Ogier Ponds CM Restoration Reach.

Sediment augmentation would continue pursuant to the Project and FAHCE Adaptive Management Program on at least a 5-year replenishment schedule for up to 20 years. The sediment volume, placement location, schedule for placement, and duration of the program may be increased or decreased and may change during adaptive management in consultation with the AMT. Sediment loads for initial placement and replenishment would be delivered by trucks, and/or transported on conveyer belts, and placed using standard construction equipment. Each sediment augmentation site would utilize existing roads and trails to the extent feasible, but establishment of access roads may be necessary to deliver sediment to the channels, which may require some minor grading and/or vegetation removal. Sediment would not be placed directly in the channel except for the toe of the sediment pile, the rest would be placed adjacent to the channel or on benches above the channel so there would be minimal impact from introducing sediment to the channel at the time of placement.

~~Sediment materials would be placed in Coyote Creek at multiple locations between the Anderson Dam and Ogier Ponds. Sediment loads would be delivered by trucks, transported on conveyer belts, and placed using standard construction equipment. Initially, the trucks would off-load approximately 500 cy of sediment downstream of the dam, near the confluence of the North and South Channels within the Live Oak Restoration Reach or Ogier Ponds. If high flow events during construction mobilize all the injected sediment within the Live Oak Restoration Reach, additional sediment would be added. Each sediment augmentation site would require the establishment of access roads (or use of existing roads and trails) and a means to deliver sediment to the channels, which may require some minor grading and/or vegetation removal.~~

Over the long term, Valley Water would maintain and adaptively manage implementation of the Sediment Augmentation Program to address and offset sediment supply and transport effects of construction and operation of Anderson Dam, and support elements of steelhead critical habitat that are maintained by sediment and geomorphic processes, including spawning gravel quality and availability and rearing habitat. Valley Water would collect the data and conduct analysis from the sediment deposition monitoring, sediment transport modeling, and long-term spawning habitat assessment monitoring. Valley Water would share this data and information and work in coordination with the regulatory agencies composing the ~~Adaptive Management Team (~~ AMT ~~)~~ to determine ~~agree, based upon such data and analysis, upon~~ appropriate injection locations, sediment volume, composition, ~~and~~ frequency of sediment augmentation, and duration of the program as required to meet the overall restoration objective of the Project and FAHCE AMP. In this way, the Sediment Augmentation Program would ~~required to~~ benefit over the long-term spawning gravel habitat and geomorphic conditions within the CWMZ without increasing flood risk or damage to infrastructure. Valley Water would conduct annual monitoring to determine the degree suitable steelhead spawning and rearing habitat remains within the CWMZ. At least every five years, Valley Water would replenish mobilized ~~spawning gravels within the Live Oak Restoration Reach by placing up to the 500 CY of~~ sediment (composition to be determined) in an amount up to 500 cy within the Live Oak Restoration Reach or Ogier Ponds CM Restoration Reach ~~within the reach~~ using the methods similar to the construction activities described for the initial placement of sediment under the Sediment Augmentation Program ~~program in Years 2 through 10, and up to Year 15~~ below, but conducted on a smaller scale suitable for replenishment. In addition, every five years Valley Water would also determine based on annual monitoring data and in coordination with the AMT whether additional sediment augmentation should ~~will~~ be conducted using similar methods to assure long-term spawning and migration habitat suitability within the Ogier Ponds CM.

The long-term, post-construction adaptive management of the Sediment Augmentation Program would be implemented pursuant to ~~in~~ the Project and ~~same manner pursuant the framework established by the~~ FAHCE AMP, which includes ~~Program, including~~ ongoing coordination of adaptive management with the regulatory agencies composing the AMT, as described in that program and in Section 2.10.

2.6.3.1 Construction Process and Phasing

Schedule

Construction activities associated with the Sediment Augmentation Program would begin following completion of ADSRP construction, including the Ogier Ponds CM and initiation of Anderson Dam post-construction operations, and would continue throughout the Project and FAHCE AMP on at least a 5-year replenishment schedule for up to 20 years ~~would occur from Year 2 through 10, and up to Year 15 as part of the Project, and continue throughout the FAHCE AMP~~.

Work Hours and Crew Size

Generally, construction activities related to injection of sediment would be conducted during a single 12-hour shift per day, between 6:00 a.m. and 6:00 p.m., Monday through Friday. ~~Equipment maintenance would occur on Saturdays, and no work would occur on Sundays.~~

An average of approximately seven workers would be required during on-site construction activities. The maximum number of workers engaged in on-site construction activities at any one time is estimated to be 15.

Typical Equipment

The types of equipment needed for construction and durations of use would vary based on the construction activity. A detailed summary of typical construction equipment required for each construction activity is provided in **Table 2-14** ~~**Table 2-15**~~.

Table 2-14 ~~2-15~~. Types of Construction Equipment – Sediment Augmentation Program

Construction Year	Construction Activity	Approximate Duration (days ~~months~~)	Equipment Type
~~Year 2~~	~~Site Mobilization~~	~~0.5~~	~~Medium bulldozer, medium excavator, motor grader, vehicle trucks, articulated dump trucks, water trucks, pumps for water trucks, and loader~~
~~Year 2~~	~~Harvest, sort, and wash in-reservoir sediments. Haul sediments to Live Oak Restoration Reach.~~	~~9~~	~~Medium bulldozer, medium excavator, motor grader, vehicle trucks, articulated dump trucks, water trucks, pumps for water trucks, and loader~~

Construction Year	Construction Activity	Approximate Duration (days ~~months~~)	Equipment Type
Post-ADSRP Construction (Initial Placement) ~~Years 2-10~~	Import sediment and place approximately 500 cy in or near the channel in the Live Oak Restoration Reach. ~~Continue to harvest, sort, and wash in-reservoir sediments. Store materials at Staging Area 6 (Holiday Lake Estates), Live Oak Restoration Reach, Ogier Ponds Staging Areas, or place directly in Coyote Creek.~~	1-2 ~~96~~	Medium bulldozer, medium excavator, motor grader, vehicle trucks, articulated dump trucks, water trucks, pumps for water trucks, and loader
Post-ADSRP Construction (Longer-term Additional Placements) ~~Years 10-15*~~	Monitor sites and continue to refresh sediment augmentation sites by placing additional sediment into Coyote Creek in the Live Oak Restoration Reach or Ogier Ponds Restoration Reach over time, as determined by monitoring.	Varies, depending on need ~~60~~	Medium bulldozer, medium excavator, motor grader, vehicle trucks, articulated dump trucks, water trucks, pumps for water trucks, and loader

Source: Valley Water 2024 ~~Biological Evaluation 2023~~

~~**Beyond Year 10 the Sediment Augmentation Program would continue through the adaptive management program*~~

~~*2.6.3.2 Site Mobilization and Preparation*~~

~~Staging Areas and Access~~

~~Sediment would be gathered from the dry lakebed of Anderson Reservoir, using the Holiday Lake Boat Ramp and Staging Area 6 (**Figure 2-4**). Access to the area would occur via Holiday Lake Drive and through the in-reservoir haul roads. Materials would then be transported to the Live Oak Restoration Reach or Ogier Ponds reach, using in-reservoir access roads or public roads (Cochrane Road, Monterey Road, Barnhart Avenue). If adequate material is not available in the reservoir, the sediment would be obtained by an offsite source.~~

~~Construction Materials and Sources~~

~~All materials would be sourced from the dry Anderson Reservoir lakebed. If adequate material is not available in the reservoir, the sediment would be obtained by an offsite source.~~

2.6.3.2 ~~Construction~~ Methods

Adequate sediment, in accordance with the Sediment Augmentation Plan, would be obtained from an offsite source and then placed in Coyote Creek within the Live Oak Restoration Reach (initial placement), or within the Live Oak or Ogier Ponds restoration reaches (longer-term additional placements). ~~The sediment would be washed and sorted on-site if sourced from the reservoir, and then placed in Coyote Creek in locations between Anderson Dam within the Live Oak Restoration Reach or Ogier Ponds.~~ Sediment loads would be delivered from offsite sources by trucks, transported by conveyer belt, and deposited with standard construction equipment.

2.6.4 Phase 2 Coyote Percolation Dam Fish Passage Enhancements

As part of the FOCP, the Coyote Percolation Dam was replaced with an inflatable bladder dam, to accommodate releases from ADTP (known as Phase 1 Coyote Percolation Dam) and to allow the more nimble operation of the dam as compared to the flashboard dam to accommodate fish migration. The Phase 2 Coyote Percolation Dam Fish Passage Enhancement CM (Phase 2 Coyote Percolation Dam CM) implemented pursuant to the Project would consist of certain fish ladder, radial gate, and concrete baffle and attractant pool adjustments to the facility as well as constructing downstream channel modifications to install a roughened ramp downstream of and approaching the dam facilitating ~~facilitate~~ upstream and downstream fish passage over the deflated bladder dam over a range of flow conditions.[18] The Phase 2 Coyote Percolation Dam CM area is located along Coyote Creek, approximately 10.5 miles downstream of Anderson Dam. The objective of this effort is to improve fish passage conditions at Coyote Creek downstream of the Coyote Percolation Dam in accordance with design and operations criteria set forth in NMFS and CDFW technical guidance. The Phase 2 Coyote Percolation Dam CM would include construction of a roughened channel (approximately 500-feet long by 110-feet wide) using some combination of grouted boulders and cobble where hardened surfaces are necessary for structural integrity and un-grouted engineered streambed materials composed primarily of natural materials (e.g., boulders, cobble, gravel, and sand) placed in such a way as to mimic the configuration of a natural streambed. The roughness elements in the reconstructed creek channel would slow water velocities and result in upstream waters to back up and increase in depth. As a result, water depths would increase and hydraulic drops would decrease in size, ultimately improving fish passage conditions within Coyote Creek at the Coyote Percolation Dam area. The fish passage improvements would be designed, ~~and~~ constructed, and operated in a manner consistent with the NMFS *Anadromous Salmonid Passage Facility Design Manual* (NMFS 2023 ~~2011~~) guidelines for "nature-like fishways" and CDFW *California Salmonid Stream Habitat Restoration Manual Part XII* (Love and Bates, 2009 ~~Flosi et al. 2010~~) guidelines for roughened channels) to provide safe fish passage conditions whether the dam is ~~in~~ inflated or deflated. Further refinements to the Phase 2 design and the Coyote Percolation Facility Operations Plan would be developed during the construction phase in consultation with the TWG.

In addition to the passage improvements associated with the Phase 2 Coyote Percolation Dam, studies on juvenile fish passage and predation risk through the pond complex would be

[18] NMFS *Anadromous Salmonid Passage Facility Design Manual* (NMFS 2023 ~~2011~~) recommends a design flow range for fishways as the mean daily average streamflow that is exceeded 95 percent (low end) to 5 percent (high end) of the time during periods when migrating fish are normally present at the site.

conducted post-enhancements to assess if changes are necessary following implementation of the facility to improve juvenile out-migration and provide a research-based assessment to make ecologically responsible decisions regarding ongoing operations and adaptive management of the facility. In coordination with the AMT, Valley Water would conduct studies to assess conditions for juvenile outmigration during operation of the Phase 2 Coyote Percolation Facility. A full study plan would be finalized in consultation with the TWG in the final year of Phase 2 construction, so implementation of the studies can occur once the Project is completed and post-construction Anderson Dam facilities operations are implemented.

2.6.4.1 Construction Process and Phasing

Schedule

Mobilization ~~Construction~~ activities associated with the Phase 2 Coyote Percolation Dam CM would begin in Year 1, and construction activities would occur during ~~the summer and fall of~~ Years 1 ~~4~~ and 2 ~~5~~ and would include site mobilization, control of flows in Coyote Creek (dewatering), demolition, vegetation clearing, and grubbing, creek material placement and enhancement, roughened ramp construction, and revegetation seeding and planting.

Work Hours and Crew Size

Generally, construction activities would be conducted during a single 12-hour shift per day, between 6:00 a.m. and 6:00 p.m., Monday through Friday. Equipment maintenance may occur on Saturdays. No construction work would occur on Saturdays and Sundays.

An average of approximately 10 workers would be required during on-site construction activities. The maximum number of workers engaged in on-site construction activities at any one time is estimated to be 20.

Typical Equipment

The types of equipment needed for each phase of construction and the durations of use of that equipment would vary based on the construction activity. A detailed summary of typical construction equipment required for each construction activity is provided in **Table 2-15** ~~**Table 2-16**~~.

Table 2-15 ~~2-16~~. Phase 2 Coyote Percolation Dam Fish Passage Enhancements Construction Sequencing and Required Construction Equipment

Construction Year	Construction Activity	Approximate Duration (months)	Equipment Type
Year 1 4	Site mobilization	3 ~~5~~	Excavator, loader, light trucks
Year 1 4	Construction of the haul roads and preparation of stockpile areas	1 0.5	Bulldozer, excavator, loader, motor grader, backhoe, haul truck, track drill rig, light trucks, dump trucks, water trucks, water pump for water trucks
Year 1 4	Clear and grub	1 ~~0.5~~	Bulldozer, loader, long-reach excavator, haul trucks, dump truck, light trucks, water truck, water pump for water truck
Year 1 4	Construct creek bypass system	1 ~~0.5~~	Loader, long-reach excavator, backhoe, haul truck, light trucks, pumps, generator (80 kW)
Year 1 4	Dewater	1	Loader, long-reach excavator, backhoe, haul truck, light truck, pumps, generator (80 kW)
Years 1 – 2 ~~Year 5~~	Facility modifications and roughened ~~Roughened~~ ramp construction	9 5	Bulldozer, long-reach excavator, backhoe, haul truck, loader, bobcat, dump trucks, light trucks, water truck, water pump for water trucks
Years 1 – 2 ~~Year 5~~	Revegetation seeding and planting	2 ~~5~~	Bobcat, loader, light trucks

Key: kW = kilowatt

2.6.4.2 Site Mobilization and Preparation

Staging Areas

Staging of construction equipment, supplies, and materials would occur at a 0.8-acres parking area, located approximately 2,200 feet southeast of the Coyote Percolation Dam (**Figure 2-3b**). The parking area is an upland site located outside of the Coyote Creek channel that is unvegetated and surfaced with crushed rock. It is located adjacent to the existing road that provides access to the Coyote Percolation Dam from Metcalf Road, a distance of approximately 5,500 feet.

The staging area would be used for equipment trailers, equipment and materials storage, equipment maintenance facilities, fuel pumps, fuel storage tanks, construction vehicle parking, and materials laydown.

Access

The Coyote Percolation Dam is accessible via Monterey Highway, a four-lane paved public road, Metcalf Road, a two-lane paved public road, and internal roads at the Coyote Percolation Dam site. The internal roads are surfaced with crushed stone, and are closed to the public for use. From the dam site, an existing concrete ramp adjacent to the north abutment of the dam provides vehicle access to the Coyote Creek channel, downstream of the dam where the roughened channel work would be constructed.

Construction Materials and Sources

Materials required for the Phase 2 Coyote Percolation Dam Fish Passage Enhancements CM would originate from commercial sources within the San Francisco Bay Area. Existing channel bed materials will be used to reshape and configure the channel bed to reduce the import of fill dirt. Existing suitable gravels and cobbles within the channel will be stockpiled and reused during construction to the extent possible. Construction of the roughened ramp will require boulders, cobbles, ~~and~~ gravels<u>, and concrete</u> totaling approximately <u>18,000</u> ~~9,000~~ cy to be hauled to the site, resulting in approximately <u>2,994</u> ~~1,110~~ <u>one-way</u> truck trips.

Table 2-18 shows the required annual number of haul trucks associated with materials delivery and offsite disposal quantities that would be hauled from the site by each construction activity.

2.6.4.3 Construction Methods

Dewatering of the CM area would be implemented through the construction of upstream and downstream cofferdams that would be constructed with a bypass feature (pipes) to allow flows to bypass the work area and maintain flows in Coyote Creek throughout Project implementation. These diverted flows would be discharged back into Coyote Creek downstream of the work area. Installation of pumps and/or temporary dewatering wells would also be necessary within the dewatered work area to control groundwater seepage and nuisance waters throughout Project implementation.

When the work area has been fully dewatered, the area would be graded and the channel contoured and enhanced. To construct the roughened channel, the creek bed would be excavated to a depth of approximately 6 feet. The volume of cut material would be approximately 9,650 ~~3,200~~ cy. The roughened channel would be composed of large (approximately 4-feet diameter) angular rocks placed intermittently within the ~~spanning the~~ bed of the creek ~~at about 40-foot intervals~~ from the downstream limit of work to the concrete slab at the dam. The volume of large rock material would be approximately 2,205 ~~2,400~~ cy. Additionally, about 9,987 ~~6,400~~ cy of engineered fill, including reused native material, would be placed within the modified area downstream of the dam ~~roughened channel~~. Through this process the existing grouted rock slope protection would be removed and replaced using heavy equipment (e.g., excavators, haul trucks, concrete trucks and pumps). A detailed summary of construction equipment that would be used for Project implementation, materials that would be required, and total haul trip required for each construction activity is provided in **Table 2-16** ~~**Table 2-17**~~.

Measures to minimize impacts to anadromous salmonids and habitat throughout dewatering activities would include biological monitoring, fish relocation, and invasive species management, during the drawdown of Coyote Creek within the work area. This work would be done in accordance with the Project Fish Rescue and Relocation Plan. In addition, all diversion pump inlets and outlets would be screened to prevent fish from being injured by any pumps used to dewater the Project Area. Water quality monitoring would also be undertaken throughout Project implementation, as discussed in Section 2.7, *Construction Phase Monitoring*. ~~in accordance with the San Francisco Bay Basin Plan Water Quality objectives (RWQCB 2022). In accordance with the San Francisco Bay Basin Plan, p~~Parameters for water quality monitoring would include temperature, total dissolved solids, and turbidity.

Table 2-16 ~~2-17~~. Summary of Phase 2 Coyote Percolation Dam Haul Truck Trips by Construction Activity

Construction Activity	Rock/Aggregate /Soil Delivery (cy)	Construction Materials/Supplies/Equipment	Total Number of Haul Truck Trips (one-way)
Site Mobilization	980 ~~0~~	Medium bulldozer, medium excavator, motor grader, track drill rig, vehicle trucks, articulated dump truck, water trucks, pumps for water trucks, and loader	21 ~~0~~
Control of Water	600 ~~0~~	Long-reach excavator, generator (80 kW), vehicle truck, articulated dump truck, water truck, pumps for water trucks, pumps for dewatering, and loader	60 ~~0~~
Demolition and Clear and Grub	0	Bulldozer, long-reach excavator, loader, vehicle trucks, and articulated dump truck	20 ~~0~~
Facility Modifications and Roughened Ramp Construction	18,066 ~~6,400 cy~~	Long-reach excavator, loader, bobcat, vehicle trucks, articulated dump truck, water truck, and pumps for water trucks	2,994 ~~1,280~~

Construction Activity	Rock/Aggregate /Soil Delivery <u>(cy)</u>	Construction Materials/Supplies/Equipment	Total Number of Haul Truck Trips <u>(one-way)</u>
Restoration Planting	<u>270</u> ~~160 cy~~	Bobcats, loaders, and vehicle trucks	<u>34</u> ~~32~~

All trips represent one-way trips to the Coyote Percolation Dam site.

Key: kW = kilowatt

<u>Note: Haul Trips increased as a result of further Project design refinement following release of the Draft EIR. Impacts related to these construction trip increases are reflected in this Final EIR, and no new or substantially more severe significant impacts are caused by these trip increases.</u>

2.6.5 Maintenance Activities at the Live Oak Restoration Reach

As part of the FOCP's HMMP, Valley Water would implement spawning gravel and rearing habitat improvements in the Live Oak Restoration Reach within the south channel of Coyote Creek, directly downstream of Anderson Dam. The implementation of restoration activities within the Live Oak Restoration Reach would enhance and restore fluvial processes, and improve habitat conditions for steelhead spawning and rearing, enhance riparian conditions, and enhance channel complexity through the placement of large woody debris and coarse sediment. These improvements would offset the potential effects of reservoir dewatering and sediment deposition on spawning and rearing habitat in Coyote Creek from the FOCP and Project by restoring over 2,800 ft of channel and creating over 20,000 square feet spawning habitat, over 65,000 feet of suitable juvenile rearing habitat, and over 20,000 square feet of shallow water habitat for fry rearing an inundated margin habitat at typical spring and summer flows (approximately <u>30-50 cfs</u> ~~30cfs~~). This effort also includes the placement of gravels and woody debris, in accordance with the HMMP, throughout the Live Oak Restoration Reach. Spawning habitat would be created through these improvements with the placement of gravel benches where steelhead eggs may be deposited and fertilized. The improvements to the Live Oak Reach would also result in the creation of spawning habitat, and rearing habitat where juvenile fish may take up residence and use the area for feeding, shelter, and growth.

During Project construction, the Live Oak Restoration Reach habitat would be monitored, and maintained to assure continuing fisheries benefits. At a minimum, Valley Water will determine, based on annual monitoring, the degree to which habitat degradation is occurring. At least every five years, Valley Water will replenish spawning gravels within the Live Oak Restoration Reach<u>. To maintain steelhead habitats, the extent of spawning gravels to replenish would be assessed during visual observations and following monitoring surveys. Inferential and calculated volumes for spawning gravel volumes would be used to evaluate the need for replenishment of spawning gravel volumes. Stockpiled spawning gravel would be added in small increments to maintain steelhead adult spawning habitat. Gravels washed thoroughly of fine sediment would be placed using silt curtains and a belting conveyor to minimize impacts to aquatic habitat</u> ~~by placing up to 500 CY of sediment (composition to be determined) within the reach using the methods similar to the construction activities described for the Sediment Augmentation Program in Years 2 through Year 10, and potentially up to Year 15, but conducted on a smaller scale suitable for replenishment~~. Additional ongoing maintenance activities that may be required in order to meet restoration goals would include the placement of additional woody debris <u>structures, boulders,</u> and gravels.

The long-term, post-construction adaptive management of the Live Oak Restoration Reach will occur in accordance with the Project and FAHCE AMP ~~the Sediment Augmentation Program and will be implemented in the same manner pursuant the framework established by the FAHCE Program, as described in that program and in Section 2.10~~.

2.7 Construction Phase Monitoring

2.7.1 Water Quality Monitoring: Water Temperature, Dissolved Oxygen, Turbidity, and pH

~~*2.7.1.1 Water Temperature and DO Monitoring*~~

Water temperature~~s, and~~ dissolved oxygen (DO), turbidity, and pH have been monitored during FOCP as part of the Condition 2 Plan and will continue to be monitored throughout construction of the Project. The water quality monitoring procedures would be documented in a Water Quality Sampling Plan.

Water Temperatures and DO monitoring would be conducted in Anderson Reservoir during the Seismic Retrofit construction (including the remaining pool, when at deadpool) to assess trends in surface temperature that will be the source of outflow to Coyote Creek until the Project is completed. An additional logger would be deployed within Coyote Creek at the upstream end of Anderson Reservoir to monitor temperature of inflow into the Anderson Reservoir. This monitoring would be used in models to help predict temperatures within Coyote Creek downstream of Anderson Reservoir. While Anderson Dam is being retrofitted, Valley Water would have limited operational flexibility associated with local flow release rates or locations of release of imported water, other than the CDL and Cross Valley Pipeline Extension. Some temperature changes may be possible within the FCWMZ via adjustments to imported water discharges from the CDL via the chillers, depending on water year/seasonal conditions.

Water temperature and ~~dissolved oxygen (~~DO~~)~~ would also be evaluated in Coyote Creek within the FCWMZ to determine if conditions are suitable for rearing of *O. mykiss* and for use in models to predict when temperatures and/or DO in the Creek may become unsuitable for steelhead. This will help determine if fish rescue is necessary and provide water temperature monitoring close to the Cross Valley Pipeline Extension, as well as gather stream temperature data for the Stream Flow and Water Temperature Forecast Model. To minimize the potential for temperature related effects to steelhead, a forecasted maximum weekly average temperature (MWAT) of 75°F (24°C) within the reach from Anderson Dam to Ogier Ponds would be assumed to represent poor conditions for steelhead rearing and would trigger the discussion with regulatory agencies about the potential need for fish rescue and relocation. Fish rescues will be conducted in coordination with the regulatory agencies at an instantaneous water temperature of 70 degrees F (21 degrees C). DO levels less than 7 mgl/L will also be considered in determining the need for fish rescue.

Continuous water temperature loggers are currently deployed at ten permanent monitoring locations on Coyote Creek downstream of Anderson Dam and, will continue to be deployed at 5 additional critical locations monitored pursuant to FOCP requirements: above and below the new imported water turnout of the Cross Valley Pipeline Extension, upstream of the Coyote

Percolation Pond, and in the North Channel. DO data will be collected at three of these stations that also have loggers for that constituent of concern.

These loggers were deployed before and as a part of the FOCP and would continue to collect data through Project construction. Daily average, maximum, and minimum temperature and MWAT, at each station, and average, maximum, and minimum DO at three stations, would continue to be reported as directed in the Temperature and Fisheries Monitoring Plan (Valley Water 2020i ~~2020e~~).

Besides water temperature and DO, Valley Water would collect other water quality data, including pH and turbidity data as part of the Water Quality Sampling Plan. Valley Water would also collect sediment data under the Sediment Deposition Plan (see Section 2.7.2) and turbidity and total suspended solids data under the Sediment Monitoring Plan (see Section 2.7.2.1). As further described in Sections 2.7.2 and 2.7.21 below, turbidity, total suspended sediment, and sediment deposition associated with releases of sediment resulting from in-reservoir construction activities, including primarily reservoir dewatering, will be monitored pursuant to the Sediment Monitoring Plan and the Sediment Deposition Monitoring Plan.

In addition, data would be collected for stormwater and runoff discharges from construction areas outside of the reservoir pursuant to a SWPPP developed in accordance with requirements set forth in the statewide Construction General Permit. The SWPPP, including construction discharge turbidity and pH monitoring that complies with the Construction General Permit, would be prepared and implemented to address construction stormwater discharges associated with out-of-reservoir seismic retrofit improvement construction activities. Should Valley Water observe water quality exceedances of the numeric actions levels specified for turbidity and pH in the Construction General Permit that are proximately caused by releases of pollutants discharged from ADSRP construction activities outside of the reservoir, then Valley Water and its contractors would comply with SWPPP conditions that implement Construction General Permit requirements. Further, the SWPPP would include water quality monitoring procedures and practices; erosion, sediment and pH control BMPs; and BMP and out-of-reservoir construction area inspection procedures to address sediment and pH. SWPPP implementation would be sufficient to address controllable turbidity and pH factors in compliance with the Construction General Permit standard and requirements. Specifically, the water quality monitoring provisions of the SWPPP would describe the turbidity and pH monitoring methods and water quality data reporting (e.g., regulatory agency reporting and frequency) as required by the Construction General Permit, including applicable requirements for analyses of exceedances; specification of sample collection and methods; procedures for sample storage, handling, and transport; and details pertaining to laboratory coordination, data management, analytical methods, and quality control.

~~Besides water temperature and DO, Valley Water may collect other water quality data (e.g., pH and turbidity). As described above, water quality data would be collected frequently, allowing for immediate review and continual tracking. Should Valley Water observe water quality exceedances based on the San Francisco Bay Region Basin Plan, Valley Water and its contractors would be responsible for inspecting the implemented BMPs to determine whether the exceedance is due to a controllable factor within the construction footprint. A water quality monitoring plan would be prepared that would outline requirements for water quality data reporting (e.g., regulatory agency reporting and frequency), including the requirements for analyses of exceedances; specify sample collection and methods; outline sample storage,~~

~~handling, and transport procedures; and include details pertaining to laboratory coordination, data management, analytical methods, and quality control.~~

This construction phase water quality monitoring and data supplements other sediment monitoring to affirm mobilization and anticipated effects of in-reservoir sediments and guide post-construction restoration as described in Section 2.7.2. It also supplements other temperature and water quality constituent monitoring conducted pursuant to FAHCE in Coyote Creek from Anderson Dam to the intertidal zone.

~~This water quality monitoring data supplements other temperature and water quality constituent monitoring conducted pursuant to FAHCE in Coyote Creek from Anderson dam to the intertidal zone.~~

2.7.2 Sediment Deposition Monitoring

Valley Water prepared a Sediment Deposition Monitoring Plan in Coyote Creek Downstream of Anderson Dam (Valley Water 2020j ~~2020i~~) for the FOCP, which Valley Water would continue to implement through construction of the Project. Sediment deposition monitoring would evaluate available habitat conditions for steelhead (spawning gravel, and monitoring sites for spawning gravel quality, egg incubation, juvenile rearing, and fish migration) using the Habitat Criteria Mapping (HCM) approach (Stillwater Sciences 2021~~a~~) within the Coyote Creek FCWMZ. Sediment deposition monitoring data would be used in conjunction with suspended sediment monitoring data collected under the Sediment Monitoring Plan (Horizon 2022) to assess and confirm anticipated ~~the~~ impacts from sediment released during FOCP and Project construction on spawning habitat quantity and quality and guide the implementation of CMs, including the Maintenance of the Live Oak Restoration Reach, Ogier Ponds, and Sediment Augmentation Program CMs, to offset those effects.

Field approaches to monitor sediment deposition in the FCWMZ would include: (1) monitoring spawning gravel quantity and quality at 31 HCM study sites, and (2) monitoring deposition effects to spawning gravel quality, egg incubation, juvenile rearing, and fish migration at transects (five transects each at three locations in the FCWMZ).

The following field methods that would be conducted at each of the habitat units sites would include use of aerial images of each habitat unit to map suitable spawning and BMI habitat area, assess impacts to spawning gravel quality, conduct surveys during typical spawning flows of around 40 to 100 cfs, and capture photographs at each habitat unit to document spawning gravel and BMI conditions.

In addition to monitoring HCM habitat units, 5 transects within each of 3 locations within the FCWMZ would be monitored annually in the spring. Results would be used to detect effects on spawning gravel quality, egg incubation, juvenile rearing and fish migration to confirm impacts of fine sediments released during and the FOCP drawdown and seismic retrofit activities, and to guide post-construction restoration and implementation of the CMs that offset these effects.

2.7.2.1 Suspended Sediment Monitoring

Valley Water's *Sediment Monitoring Plan* (Horizon 2022) prepared for the FOCP would continue to be implemented throughout construction of the Project. The plan's focus is to continuously monitor suspended sediment discharges from Anderson Reservoir to evaluate the effect of the discharges on Coyote Creek fisheries habitat downstream of the dam. The monitoring data would also be used to help evaluate the effect of the discharges on Coyote Creek baylands habitat downstream of the dam. Continuous turbidity monitoring (15-minute intervals), suspended sediment concentration (daily intervals), and suspended load (daily intervals) would be collected in Coyote Creek, including in the FCWMZ.

~~Valley Water would implement a Sediment Monitoring Plan to continuously monitor suspended sediment discharges from Anderson Reservoir through completion of Project construction activities, and to monitor the effect of the discharges on Coyote Creek downstream of the dam. Continuous turbidity monitoring equipment (15-minute intervals) was installed in the FCWMZ as part of the FOCP. Valley Water would use collected data, in combination with sediment deposition data collected as part of sediment deposition monitoring (described below) to develop a sediment rating curve at several locations on Coyote Creek.~~

Valley Water contracted with United States Geological Survey (USGS) to collect continuous turbidity and suspended sediment monitoring data at four locations:

- **Madrone Gage (USGS 11170000)**: This site is in Morgan Hill downstream of the confluence of the historic northern channel and existing southern channel and is within the primary steelhead rearing habitat within the FCWMZ.
- **Coyote Ranch Road Gage (USGS 11170450):** This site is in Coyote upstream of the Coyote Percolation Pond where Coyote Ranch Road crosses Coyote Creek (wet conditions data).
- **Edenvale Gage (USGS 11171500):** This site is in San Jose in the Edenvale neighborhood, adjacent to Fonick Drive (wet conditions data).
- **Highway 237 Gage (USGS 11172175)**: This site is in Milpitas on the upstream side of Highway 237.

~~Monitoring locations used to collect continuous turbidity data and periodic sediment grab samples include the following:~~

- ~~**Serpentine Trail Pedestrian Bridge**: grab samples for suspended sediment characterization, temporary/baseline turbidity monitoring, conductivity/ total dissolved solids measurements during grab sampling. Samples already collected, on 1/4/21 and 1/27/21 were not measurable due to the relatively dry conditions.~~
- ~~**Valley Water Gage Station #5082**: continuous turbidity probe (15-minute intervals). This site is located downstream of the confluence of the historic northern channel and existing southern channel and of planned ADTP construction areas and is within the primary steelhead rearing habitat within the FCWMZ. Telemetry will be used at this site to provide real-time data.~~
- ~~Downstream end of dam release chute: visual monitoring for accumulation or larger sediment grain sizes.~~

In addition, supplemental turbidity and total suspended sediment concentration data would be collected by Valley Water near the Anderson Outlet during and/or following storm events. This suspended sediment monitoring data would be used together with the data collected under the Sediment Deposition Monitoring Plan to assess and confirm the anticipated the impacts from sediment released during FOCP and Project construction on spawning habitat quantity and quality and guide the implementation of CMs, including the Maintenance of the Live Oak Restoration Reach, Ogier Ponds, and Sediment Augmentation Program CMs, to offset those effects.

2.7.3 Groundwater Monitoring

2.7.3.1 Wetland and Habitat Riparian Dryback Plan

Valley Water's *Wetland and Habitat Riparian Dryback Plan* (Valley Water 2020b ~~2020f~~) and *Groundwater Management Plan* (Valley Water 2021g ~~2023e~~) would continue to be implemented; this includes groundwater monitoring, monitoring of groundwater-dependent habitat types (e.g., riparian and wetland habitat), and monitoring of groundwater recharge from the CDL downstream to Coyote Creek streamflow gauge #5058 ~~(Edenvale gauge, **Figure 3-1**)~~.

2.7.3.2 Groundwater Management Plan

As part of the Groundwater Management Plan, regional groundwater monitoring would provide real-time assessments for how the Project is impacting groundwater recharge and existing water basin sustainability goals, and include programs to monitor groundwater levels, land subsidence, groundwater quality, and surface water. For this effort, Valley Water would use their existing network of water level and water quality monitoring wells, including wells installed by Valley Water, existing wells Valley Water has obtained, and privately-owned wells for which Valley Water has secured monitoring access, and supplemental data collected by water retailers to facilitate a comprehensive understanding of groundwater conditions. Project monitoring activities would comply with Valley Water's existing Groundwater Management Plan, which establishes the agency's monitoring network, provides guidance on frequency, monitoring parameters, monitoring protocols, and sampling methodologies. Groundwater conditions are reported in Valley Water's annual groundwater report and SGMA water year report. Based on the results of the monitoring, Valley Water would seek to adjust the imported water releases and/or pursue water use reduction measures to alleviate or correct any identified deficiencies or negative trends in groundwater storage.

2.7.4 Vegetation Monitoring

2.7.4.1 Phytophthora Pathogen Management and Monitoring

Phytophthora is a taxonomic group of microscopic oomycetes (also known as water molds) that cause plant diseases such as root rots, stem cankers, and fruit and leaf blights. *Phytophthora* is transmitted through the movement of contaminated soil, water, and plant material, although some species are known to be airborne.

Based on the *Phytophthora Pathogen Management Plan* (Valley Water 2020c ~~2020g~~) and *Post-Project Phytophthora Monitoring Plan* (Valley Water 2021d ~~2021h~~), Valley Water would implement plans to prevent, avoid, and/or minimize the spread of *Phytophthora* infestations as a result of construction and Project ~~project~~-related activities. Management and planning would involve the evaluation of site conditions prior to Project construction (i.e., existing contaminated sites), identification of sensitive plant species and communities, identification of Project activities that have the potential to spread *Phytophthora*, and the implementation of Project

~~project~~-specific measures (e.g., hygiene and sanitation, access and movement, vegetation disposal, soil transport, and revegetation) to prevent the spread of *Phytophthora* by the Project.

2.7.4.2 Wetland and Riparian Habitat Dryback Monitoring

Valley Water's Wetland and Riparian Habitat Dryback Monitoring Plan prepared for the FOCP (Valley Water, 2020b ~~2020f~~) would continue to be implemented throughout Project construction. The plan's focus is to monitor and manage groundwater recharge and avoid or minimize dryback conditions and impacts to wetlands and riparian habitats within Coyote Valley due to a reduced flow in Coyote Creek and a reduction in shallow groundwater levels in Coyote Valley during and after FOCP and during Project construction.

The conditions of habitats would be monitored along Coyote Creek and within a portion of Coyote Valley to determine if there is a reduction in the surface area of wetlands and/or riparian habitats due to Project construction-related dryback. Aerial imagery, site visits, and photo documentation would be utilized to collect baseline (post-FOCP), interim, and after Project completion vegetation information. If early signs of dryback are observed during monitoring, Valley Water would determine whether different management of imported water releases during the construction and reservoir drawdown period could be used to reduce the impacts (i.e., increasing release rates of imported water).

2.7.4.3 Milkweed Monitoring

Valley Water would continue to implement the Milkweed *Survey* ~~Monitoring~~ Plan that was developed for the FOCP (Valley Water, 2020d) through the completion of Project construction, or until the monarch butterfly is added to the VHP as a covered species. Milkweed are known to be present at scatter locations along Coyote Creek downstream from Anderson Dam. Valley Water would conduct surveys for milkweed prior to the start of any ground disturbance or vegetation removal activities. A qualified biologist would survey the footprint of all potential impact areas, plus a 25-foot buffer around each impact area, for milkweed plants. If any milkweed is found, it would be avoided, if feasible. If avoidance is infeasible, the milkweed would be inspected for monarch eggs or larvae, and if any of these are found, Valley Water would consult with USFWS to discuss recommendations and approach to minimize impacts. If and when the monarch butterfly is added to the VHP as a covered species, as proposed in an amendment currently being prepared, Valley Water's compliance with all monarch-related VHP conditions would supersede continued implementation of the *Milkweed Survey Plan*.

2.7.5 Fisheries Monitoring

Fisheries monitoring identified for the Project is described in the following sections.

~~Fisheries monitoring identified for the FOCP, including the *Water Temperature and Fisheries Monitoring Plan* (Valley Water 2020e) will be implemented until completion of Project construction. Similarly, fisheries monitoring described in the *Fish Rescue and Relocation Plan* (Valley Water, 2020c), and *the Fyke Trapping and Passive Integrative Transponder (PIT) Tag Monitoring Plan* (Valley Water 2021c).~~

2.7.5.1 Migration Flow Monitoring

Flows within the FCWMZ will be monitored for potential migration flows through Project completion. Following dewatering in October 2020, Anderson Reservoir can no longer be managed for storage. Without Anderson Reservoir storage, natural precipitation events are the primary source for migration flows within the FCWMZ, and they are anticipated to be sufficient to support migration of *O. mykiss* downstream and out of the FCWMZ.

2.7.5.2 Juvenile Rearing Studies

Based on the success of previous *O. mykiss* sampling efforts in the Coyote Creek Watershed, multi-pass depletion backpack electrofishing would be implemented. Juvenile rearing sampling would occur in the early summer and fall of each year as defined by Valley Water's Section 10(a)1(A) recovery permit (between June 15 and November 30) between Anderson Dam outlet and Ogier Ponds. Data collection in the fall would allow temperature requirements associated with the permit to be met and would provide information on whether summer rearing occurred based on presence of *O. mykiss*. It would also help reveal if successful reproduction occurred if young-of-the-year sized fish are present. Sampling in early summer (after June 15) would allow for better estimates of juvenile production, growth, and survival during the summer months if temperature conditions allow for sampling (Valley Water 2023a ~~2023b~~).

2.7.5.3 Migration Study

During the juvenile rearing monitoring, Juvenile *O. mykiss* would be tagged with PIT tags if they have not already been tagged. Valley Water can currently tag up to 100 individuals within Coyote Creek in accordance with the Section 10(a)1(A) recovery permit. PIT tag numbers and associated biological data for all recaptures and fish tagged by Valley Water in Santa Clara County would be recorded and kept in an online database at Valley Water. All PIT tagging would be conducted in accordance with the PIT Tag *Marking Procedures Manual* (Columbia Basin Fish and Wildlife Authority [CBFWA] 2014 ~~1999~~) by staff trained in the procedure. Stationary antennas located throughout Coyote Creek would allow for movement to be tracked to develop a better understanding of migration timing and the proportion of the population that is out-migrating.

2.7.5.4 Growth Comparative Study

This juvenile rearing monitoring will allow Valley Water to compare fish lengths and change in length distribution for juvenile steelhead across years. Length distribution within cohorts will be compared to pre-FOCP data using an appropriate statistical test to determine changes in size distribution since the initiation of the FOCP. The analysis of relative growth will indicate the percent increase in fish size between sampling efforts, standardized for time at large (Stillwater Sciences, 2007).

2.7.5.5 Environmental DNA Monitoring

Environmental DNA (eDNA) monitoring is described in both the *Fish Rescue and Relocation Plan* (Valley Water 2020e ~~2020c~~) and the *Water Temperature and Fisheries Monitoring Plan* (Valley Water 2020i ~~2020e~~). To increase the probability of detection and limit the handling of threatened CCC steelhead, eDNA sampling would be conducted through construction of the Project to monitor for the presence of *O. mykiss* in the FCWMZ.

Water samples would be collected from eight spatially distributed locations throughout the FCWMZ, as well as from Upper Penitencia Creek and Anderson Reservoir to serve as positive controls for eDNA detection. Samples would be collected every 2 weeks from May through September, when temperature conditions may be nearing stressful levels for *O. mykiss* in the FCWMZ.

~~2.7.5.6 Fyke Trap Monitoring~~

~~When conditions allow, a fyke trap would be installed downstream of the Anderson Reservoir outlet to sample fish passing through the release location and intercept non-native fish. In 2021, the *Fyke Trapping and PIT Monitoring Plan* implementation began as part FOCP as ordered by FERC, and the fyke trapping at the outlet of the reservoir was extended (Valley Water 2021c). A fyke net is a fish trap consisting of cylindrical or cone-shaped netting bags mounted on rings or other rigid structures. The fyke net would be located within a suitable location downstream of the South Channel canal where the net would be able to capture the flow from the Anderson outlet. The fyke net would be constructed from quarter-inch mesh and fixed on the bottom by anchors, ballasts, or stakes. The trap is susceptible to being rendered inoperable due to high flows and debris clogging the wings and trap.~~

~~The trap would be operated up to 5 days per week and checked at least daily. All terrestrial and amphibian species captured would be returned to Coyote Creek downstream of the fyke. All captured fish would be held in aerated containers or the trap prior to being identified, enumerated, and measured prior to release. All resident *O. mykiss* and other native species would be released in the main body of Anderson Reservoir. Permits were obtained in 2022 to dispatch non-native amphibian and reptile species (American bullfrog [*Lithobates catesbeianus*] and red-eared sliders [*Trachemys scripta*]) as well as non-native predatory fish.~~

2.7.5.6 VAKI Riverwatcher Adult Escapement Monitoring

VAKI adult escapement monitoring, to evaluate the escapement of adult steelhead into the CWMZ of Coyote Creek, is described in the *Water Temperature and Fisheries Monitoring Plan* (Valley Water 2020i ~~2020e~~). This monitoring would be conducted until the Project is completed to help determine if adult steelhead effectively migrate through the lower reaches of Coyote Creek and are potentially spawning within the FCWMZ. This would help determine if fish are using the reach and would inform fish rescue planning.

VAKI is a computer-based fish counter. The VAKI system is designed to track adult migratory fish (greater than 1.6 inches body depth) with a clear migratory path (i.e., anadromous fish). The system does not provide the ability to estimate the number of fish using the habitat that the system is installed in, nor does it track juvenile movement patterns. It employs scanner plates and a digital camera to capture videos and silhouette images of fish as they pass between the plates. The speed, direction, body depth, date and time are all captured for each event.

The VAKI unit on Coyote Creek would be installed at the Coyote Percolation Dam facility within the fish ladder. The percolation dam fish ladder is located approximately 31 miles upstream of the South San Francisco Bay on Coyote Creek between Metcalf Road and US 101, just downstream of Coyote Percolation Ponds. Video images and silhouettes would be used to identify fish to species when possible. Detailed methods are included in the *Water Temperature and Fisheries Monitoring Plan* (Valley Water 2020i ~~2020e~~).

2.7.5.7 Fish Rescue and Relocation

If monitoring of water temperature and DO indicates that conditions for rearing steelhead would become unsuitable within the Coyote Creek FCWMZ as a result of construction activities, a steelhead rescue and relocation effort would be conducted per the *Fish Rescue and Relocation Plan* prepared by Valley Water in consultation with, and approved by, NMFS, USFWS, and CDFW (Valley Water 2020e ~~2020c~~). Capture methods would include backpack electrofishing and seine nets. All *O. mykiss* captured during Coyote Creek rescue and relocation efforts would be relocated to appropriate locations elsewhere in the watershed in consultation with NMFS, USFWS, and CDFW, such as Lower Coyote Creek near the confluence of Upper Penitencia Creek or Upper Penitencia Creek within Alum Rock Park.

Backpack electrofishing would be used to capture fish during rescue efforts. Battery operated backpack electrofishers would be used at all sites with a minimum of two netters per electrofisher. Prior to each electrofishing session, stream conductivity and temperature measurements would be taken and the electrofisher unit settings would be adjusted accordingly to minimize damage or mortality to fish encountered. Stunned fish would be placed in an aerated holding tank and be allowed to recover from electrofishing effects. Electrofishing would be conducted in an upstream manner at each site. Seine netting may be used to capture fish where electrofishing is not feasible. Nets up to 30 feet in length with quarter-inch delta mesh would be used. Rescue efforts would be conducted early in the day as feasible to reduce exposure to high water temperatures and would occur when temperatures are less than 21°C.

In addition to the *Fish Rescue and Relocation Plan* for Seismic Retrofit construction, other localized dewatering activities occurring in wetted habitats would require that the construction contractor prepare and submit a separate detailed dewatering and aquatic species rescue and relocation plan for review and approval by NMFS and CDFW 30 calendar days prior to initiation of activities associated with localized dewatering in Coyote Creek (e.g., prior to placement of a cofferdam, dike, stream bypass, dewatering pump). Details of the measures required to protect native aquatic species and dispatch non-native aquatic species during the localized dewatering occurrences would depend on the approach taken by the construction contractor to manage water at these locations, but would generally incorporate relevant elements of the requirements for aquatic species relocation and dewatering activities included in the NMFS (2016) Programmatic Biological Opinion for restoration projects in the National Oceanic and Atmospheric Administration (NOAA) Restoration Center’s Central Coast region.

2.7.5.8 Spawning Surveys

The purpose of the spawning surveys is to evaluate adult steelhead spawning distribution in the CWMZ of Coyote Creek. This monitoring would help determine if adult steelhead successfully constructed salmonids egg deposits (redds) and provide insight on the location of spawning activity. Spawning surveys would also inform fish rescue planning and if there is need for additional information studies.

Spawning surveys would be performed from December to April, if adult steelhead (greater than 13.8 inches) are detected at the VAKI and stream conditions allow for surveys to be performed (adequate visibility and wadable flow conditions). If outages occur, conditions reduce data quality, or if the quantity of data collected by the VAKI cannot be reviewed in 1 week, spawning surveys would be implemented, within a week of identifying the issue. Surveys would also be conducted monthly from January to April in each year of the FOCP if connectivity to San Francisco Bay occurs. Surveys would be conducted from downstream to upstream, covering spawnable reaches between Metcalf Road and Anderson Dam. Spawning surveys would be conducted downstream of the Coyote Percolation Dam fish ladder if repeat detections of up and downstream movement on the VAKI occurs, appearing to be the result of impassability (Valley Water 2021e ~~2021c~~).

2.7.6 Reptile Monitoring

2.7.6.1 Western Pond Turtle Monitoring

A *Western Pond Turtle*[19] *Monitoring Plan* (Valley Water, 2020f ~~2020h~~) was prepared for the FOCP. Similar monitoring efforts, defined through consultation with CDFW, USFWS, and the SCVHA, would continue through Project construction. In coordination with these agencies, Valley Water would continue to implement western pond turtle (*Emys marmorata pallida*) monitoring efforts in suitable habitat in the FCWMZ. The purpose of the monitoring would be to determine if a significant reduction in western pond turtle populations has occurred from Project construction. Monitoring efforts would include surveys and reporting for western pond turtle in Coyote Creek. Surveys would be conducted on sunny days from mid-morning to late afternoon to standardize conditions among surveys.

2.7.6.2 Invasive Species Monitoring

Valley Water prepared an *Invasive Species Monitoring and Control Plan* (Valley Water 2020g ~~2020k~~) for the FOCP that would continue to be implemented through construction of the Project. The species targeted by the plan include non-native fish, crayfish (*Cambaridae*), American bullfrog (*Lithobates catesbeianus*), and red-eared sliders (*Trachemys scripta*), as well as opportunistic removal of other non-native species. The non-native fish species that pose the most significant risk to native fish and wildlife are the predatory largemouth bass (*Micropterus salmoides*), spotted bass (*Micropterus punctulatus*), green sunfish (*Lepomis cyanellus*), bluegill (*Lepomis macrochirus*), crappie (*Poxomis* spp.) and catfish (*Ictalurus* and *Ameiurus* spp.) species. Because these target species are widespread and the Project Area is not a closed system, complete eradication or control is not anticipated.

Proposed control methods would include the following:

- Decontamination protocols to prevent the spread of chytrid (Bd), ranavirus, other pathogens, and non-native invasive species
- Measures to capture and dispatch non-native aquatic species would include humane euthanasia and removal of carcasses. Methods may include multi-pass depletion electrofishing, seine nets, dipnets, and hand capture

[19] On October 3, 2023, USFWS proposed to list this species as threatened and adopt an ESA section 4(d) rule to prohibit its take. Pursuant to the proposed rule, this species is now referred to in Northern California as the Northwestern Pond Turtle. See proposed rule at https://www.regulations.gov/document/FWS-R8-ES-2023-0092-16388.

- Any non-native species incidentally collected during fisheries monitoring efforts for the Project would be humanely euthanized and carcasses disposed
- Preventative controls at various locations may include signage discouraging release of unwanted pets.

2.7.7 Terrestrial Animal Monitoring

Valley Water would continue to conduct surveys for several terrestrial animal species that occur during the FOCP. Annual surveys for nesting bald and golden eagles, which include ground-based and helicopter surveys within 1 mile of all Project areas at Anderson Dam, 1 mile of the Anderson Reservoir shoreline, and 2 miles of blasting areas at Basalt Hill, would be conducted throughout Seismic Retrofit construction during the eagle breeding season. Annual surveys for pallid bats roosting in the Cochrane Road barn, which include a survey on a warm June evening to count the number of adult females exiting the maternity roost, would continue to be conducted throughout Seismic Retrofit construction. During the FOCP, Valley Water is implementing the CDFW-approved FOCP Crotch's Bumble Bee Avoidance Plan (Valley Water 2024), which includes measures to survey for Crotch's bumble bees and their nests, avoid active nests and individuals if they are detected, and minimize impacts on the species' floral resources. Valley Water would continue to implement this Plan during Project construction, as long as the species is legally protected or unless and until the Crotch's bumble bee is added to the VHP as a covered species. If and when the Crotch's bumble bee is added to the VHP as a covered species, as proposed in an amendment currently being prepared, Valley Water's compliance with all VHP conditions related to this species would supersede continued implementation of the Crotch's Bumble Bee Avoidance Plan.

2.8 Post-Construction Anderson Dam Facilities Operations and Maintenance

Following the completion of Seismic Retrofit components, post-construction operations of Anderson Reservoir would begin. Anderson Reservoir would be restored to its existing (unrestricted) capacity and allowed to withstand a normal operational range of water levels in the reservoir. Storage of water would resume, and water releases to Coyote Creek would resume from the reservoir using water originating from rainfall in the watershed, inflows from the Coyote Reservoir upstream of Anderson Reservoir (which would continue to be operated as it was prior to the issuance of the FERC Order), and imported water from the U.S. Bureau of Reclamation's San Felipe Division of the CVP (either delivered into Anderson Reservoir and released from there, or released from the Coyote Discharge Line directly to Coyote Creek). Operations and maintenance activities associated with the Project would not result in growth inducing impacts as all activities would be performed by existing Valley Water staff, County Parks, and/or other entities.

The following sections describe how the Anderson Reservoir would be operated following the new operational flexibility afforded by the seismic retrofit improvements and Valley Water's implementation of the FAHCE rule curves.

2.8.1 Reservoir Refilling and Inflow

During Year 6 of Project construction, with the approval of applicable dam safety regulatory agencies, the reservoir would be allowed to start filling to an unrestricted maximum of crest level (elev. 627.8 feet) to prepare for post-construction operations. Inflow into Anderson Reservoir would come from three sources:

(1) Uncontrolled natural inflow from the tributaries surrounding Anderson Reservoir (such as Packwood Creek and Las Animas Creek), excluding flows from Coyote Reservoir

(2) Flows from Coyote Reservoir (controlled releases pursuant to normal baseline operations from the dam outlet and uncontrolled flow when the Coyote Reservoir is spilling)

(3) Depending on availability, imported water that could be transferred into Anderson Reservoir via the Cross Valley Pipeline and Anderson Force Main through the conveyance pipeline within the LLOW

Natural inflows into Anderson Reservoir vary greatly, depending on weather and rainfall patterns. In normal water years, monthly uncontrolled natural inflow to Anderson Reservoir ranges from 8 AF in the late summer (September) to 2,489 AF in the winter (February). In wet water years, monthly natural inflow ranges from 129 AF in the late summer to 11,070 AF in the winter. In dry water years, monthly inflow ranges from 0 AF in the early fall to 215 AF in the early spring (April).

Inflows to Anderson Reservoir from Coyote Reservoir also vary, depending on water losses from the reach of the creek that spans the two reservoirs. The losses consist mainly of evapotranspiration, which average a reduction in 1-2 cfs of inflow depending on the season.[20]

Restoring reservoir operations would depend on how quickly the reservoir can refill. This may occur in a single wet season depending on watershed inflows. Once the reservoir is refilled to operable levels, FAHCE operational rule curves would be implemented, as described in Section 2.8.3.

After the constructed dam is deemed safe and the reservoir has filled, the reservoir surface area would be approximately 1,250 acres at the spillway crest level (El. 627.8 feet), with a maximum storage capacity of approximately 88,800 AF.

2.8.2 Reservoir Outflow

Following completion of the seismic retrofit construction, outflows from Anderson Reservoir would occur in four ways: (1) normal releases, up to 170 cfs to Coyote Creek via the 33-inch bypass pipeline (part of the LLOW); (2) releases up to 1,315 cfs to Coyote Creek through the 78-inch ~~through the 78-inch~~ conveyance pipeline (also part of the LLOW, and is the pipeline that facilitates bi-directional transfers of water between Anderson Reservoir the raw water

[20] Evapotranspiration is the process by which water is transferred from the land to the atmosphere by evaporation from the soil and other surfaces and by transpiration from plants. Evaporation in Anderson Reservoir depends on the fluctuations in water temperature, whether it is a dry, median or wet year, and other factors including wind speed, water surface area, and ambient air temperature. Anderson Reservoir evaporation occurs at an average rate of approximately 3.3 inches per month. Transpiration by plants is considered minor relative to evaporation.

distribution system); (3) releases up to 5,300 cfs from the HLOW; and (4) uncontrolled releases from the spillway. These four methods of outflow are summarized in **Table 2-17** ~~Table 2-18~~.

Releases to Coyote Creek during normal dry season operations of Anderson Reservoir would range from 2 to 90 cfs through the bypass pipeline, which would flow to the South Channel of Coyote Creek. During normal wet season operations, the LLOW could release up to 1,485 cfs when the reservoir is full in order to follow the 1982 flood risk reduction rule curve (see Section 2.8.3 for a description of the Post-Construction Operational Rule Curves). During higher releases, flows may be split between the North and South Channels due to a system of weirs that were installed as a part of the ADTP to avoid erosive flows in the South Channel. When flows exceed approximately 230 cfs, the north weir would be overtopped and the North Channel would be activated; the two channels would converge approximately 1,000 feet downstream where the capacity of the Coyote Creek channel is increased.[21]

The HLOW would not be operated during normal operating conditions. Instead, it would be used in the event of an emergency to make controlled emergency releases up to 5,300 cfs.[22] In an event when an emergency drawdown is warranted, as directed by DSOD, the LLOW and/or the HLOW could be used to rapidly draw down the reservoir.[23] During wet years, the reservoir may fill faster than the LLOW can release water, causing the reservoir to overtop the spillway and result in uncontrolled releases to Coyote Creek. Historically, Anderson Reservoir fills and spills about every 10 years, which has resulted in releases of approximately 7,400 cfs. Reservoir spills are expected to occur less frequently after completion of the Project; however, uncontrolled releases from the spillway would likely continue in wet years, approximately every 20-25 years.

[21] After the dam was built in 1950, the South Channel was created to connect the Anderson Dam outlet system to Coyote Creek and the previous creek alignment (now referred to as the North Channel) was diked. The South Channel capacity was shaped by releases from the dam (historically did not exceed approximately 450 cfs), while the channel downstream of the North and South Channel confluence was influenced by the periodic spillway releases which created a higher capacity channel.

[22] An emergency is a condition that presents a risk to public safety.

[23] DSOD guidelines require these outlets to be sized to lower the top 10 percent of the reservoir within 7 days, which requires average releases of 1,660 cfs. Over a 7-day period, the average LLOW releases are estimated to be 1,100 cfs and the HLOW would be used to supplement LLOW releases to reach the drawdown target within 7 days, which would require in an additional 560 cfs being released from the HLOW for the same 7-day period.

Table 2-17~~2-18~~. Summary of Post-Construction Outflows from Anderson Reservoir

Project Component	Operation Summary
LLOW – Conveyance Pipeline	78-inch outlet pipe with its own 3 intake ports at different elevations approximately elevations 488 ~~490~~ ft., 528 ft, and elev. 563 ft); screened to prevent fish from passing downstream. 54-inch fixed cone valve flows that range from up to 1,130 cfs, ~~and~~ a 42-inch sleeve valve with a flow range of 2 to 540 cfs, and a 30-inch bypass sleeve valve with a flow range of 2 to 170 cfs. With inputs from the bypass pipeline and with a full reservoir, in total the LLOW could release up 1,485 cfs (reflects system design and does not equal the sum of individual valve capacities) Releases may be made to: (i) Coyote Creek, (ii) the Raw Water Distribution System via the Anderson Force Main, and/or (iii) the Main Avenue Pipeline Imported water can be transferred to/from Anderson Reservoir via the Anderson Force Main
LLOW- Bypass Pipeline	Sloping 33-inch outlet pipe with its own 3 intake ports (as described above) 30-inch sleeve valve with flow range of 2 to 170 cfs Releases to Coyote Creek only Can be operated independently of the LLOW conveyance pipeline, which allows flows to move to/from the Raw Water Distribution System while maintaining environmental releases to Coyote Creek
HLOW	13-foot concrete pipe with independent intake port at elev. 528 feet Empty during normal operations Releases only in the event of an emergency, with a maximum discharge of 5,300 cfs 24-inch sleeve valve with maximum discharge of 250 cfs; recommend 60 cfs (20 fps through valve) Releases to Coyote Creek only
Spillway	Uncontrolled releases occur over the spillway when the reservoir is spilling at elev. 627 feet. Designed to pass extreme events, including the PMF

Key: cfs = cubic feet per second; elev. = elevation; HLOW = high-level outlet works; LLOW = low-level outlet works; PMF = probable maximum flood

2.8.3 Post-Construction Operational Rule Curves

Post-construction Anderson Reservoir operations would be governed by the FAHCE *Settlement Agreement* rule curves[24] and the Delta Reform Act of 2009 limiting use of Delta imported water supplies primarily to enhance instream habitats in other regions. Operations pursuant to the FAHCE rule curves achieve specific criteria or purposes (e.g., groundwater recharge, incidental beneficial impacts for fisheries populations, sufficient water supply, incidental flood control management).

The FAHCE rule curves are intended to provide suitable spawning and rearing habitat within the Coyote Creek Watershed, providing adequate passage for adult steelhead and salmon to reach suitable spawning and rearing habitat, and for the out-migration of juveniles. The FAHCE rule curves would add operational criteria that benefit steelhead and salmon populations by providing winter base flows, pulse flows, and summer releases to support each steelhead life stage, as well as by providing a framework for ramping pulse flows and reservoir operations under low-flow conditions. The implementation of FAHCE rule curves would differ under dry-year, median-year, and wet-year conditions. These water year types correspond to 90 percent exceedance probability (EP) (dry year), 50 percent EP (median year), and 10 percent EP (wet year), respectively.

These rates were calculated so that the minimum release rates for each type of release could be met in 90 percent of historic water year conditions. That is, the calculations used to determine the rule curves relied upon a reservoir storage volume that was documented to occur in 90 percent of all water years on record for Anderson Reservoir and Coyote Reservoir, so minimum release rates based on those storage volumes would occur in 90 percent of historic water year conditions [25]. At least 30 years of historic data were used in the hydrologic modeling to develop the EPs. This does not mean that flow management is guaranteed in 90 percent of all years; rather, the rule curves were developed to meet flow-based obligations consistent with 90 percent of all water years in the current dataset. Rule curves are shown in **Figure 2-13 and Figure 2-14**; post-construction releases are summarized in **Table 2-18** ~~Table 2-19~~ below. Imported water that is moved into Anderson Reservoir would not contribute to the combined storage calculations.

[24] A *rule curve* is a tool used to guide reservoir operations by prescribing releases from a dam based on storage levels. A rule curve indicates the minimum water level requirement in the reservoir at a specific time to meet the needs for which the reservoir is designed.

[25] The FAHCE Rule Curves rely on the combined storage of Anderson and Coyote Reservoirs. These two reservoirs must contain a minimum of 20,000 AF for emergency storage and a maximum of 113,597 AF. Coyote Reservoir has a storage capacity of approximately 22,541 AF, but is under a ~~permanent seismic~~ restriction by DSOD which limits its storage to approximately 11,843 AF.

Table 2-18 ~~2-19~~. Summary of Anderson Reservoir Operations Under FAHCE Rule Curves

Flow Release	Time Period	Summary Description
Winter base flows	November 1 – April 30	Releases intended to improve winter and springtime habitat for salmonids, maintain groundwater recharge, meet minimum bypass flow requirements, and provide incidental flood risk reduction. Release rate will depend on storage levels as shown in **Table 2-23**, with the required minimum combined storage of Anderson and Coyote Reservoirs ranges from 20,866 acre feet (November 1) to 22, 763 acre feet (May 1), which would initiate a 5 cfs base flow (as measured at Stream Gage 5082, Coyote Creek at Madrone). The maximum winter base flow release rate of at least 26 cfs would be initiated when combined storage totals 31,050 acre feet (November 1 through May 1).
Spring pulse flows	February 1 – April 30	Pulse flows to improve passage conditions for migrating steelhead and Chinook salmon. Only made when the combined storage of Anderson and Coyote Reservoirs exceed 80,000 AF and it is safe to do so, releases of 50 cfs for a period of 5 consecutive days (as measured at Stream Gage 5082, Coyote Creek at Madrone) would be carried out twice during the time period.
Summer base flows	May 1 – October 31	Releases intended to enhance summer rearing conditions for steelhead, with the target of maintaining a daily average temperature of 64.4°F (18°C) in as much of the CWMZ as possible.
Flow ramping	Year round	Decreases in releases done in a gradual manner to minimize impacts on aquatic species; this would include lowering release rates so that water flows recede in a slow, stepwise fashion to provide time for fish and other aquatic species to adapt and avoid stranding.

Key: °C = degrees Celsius; °F = degrees Fahrenheit; AF = acre-feet; cfs = cubic feet per second; CWMZ = cold water management zone

2.8.3.1 Proposed Winter Releases

Winter base flows are releases made between November 1 and April 30 to manage aquifer recharge while improving winter and springtime habitat for salmonids and providing flood risk reduction, and protecting cold water storage for the summer release program. The winter base flow releases are determined from the combined storage of Anderson and Coyote Reservoirs.

These releases may be made from Anderson Reservoir (typically from the Bypass Pipeline of the LLOW) or the CDL (which releases imported water via the Cross Valley Pipeline and SCC to Coyote Creek), or some combination provided the total required release is made. The temperature of both Anderson Reservoir releases and imported water releases is typically 57.2°F (14°C) or less during the period of November 1 through April 30; imported water releases to Coyote Creek would not be made if doing so would cause the temperature of blended sources to exceed 57.2°F (14°C) at the CDL release point. Winter base flows would be managed according to rule curves displayed in **Figure 2-13** and described in **Table 2-19** ~~**Table 2-20**~~. For these releases (and all releases discussed below), any use of imported water to meet an operational commitment in lieu of local supply from Anderson Reservoir would result in the reclassification of an equivalent volume of local water in Anderson Reservoir from local water to imported water for the purpose of applying the Reservoir Reoperation Rule Curves.

Figure 2-13. Anderson-Coyote Reservoirs Combined Storage Rule Curves: FAHCE Winter Base Flows

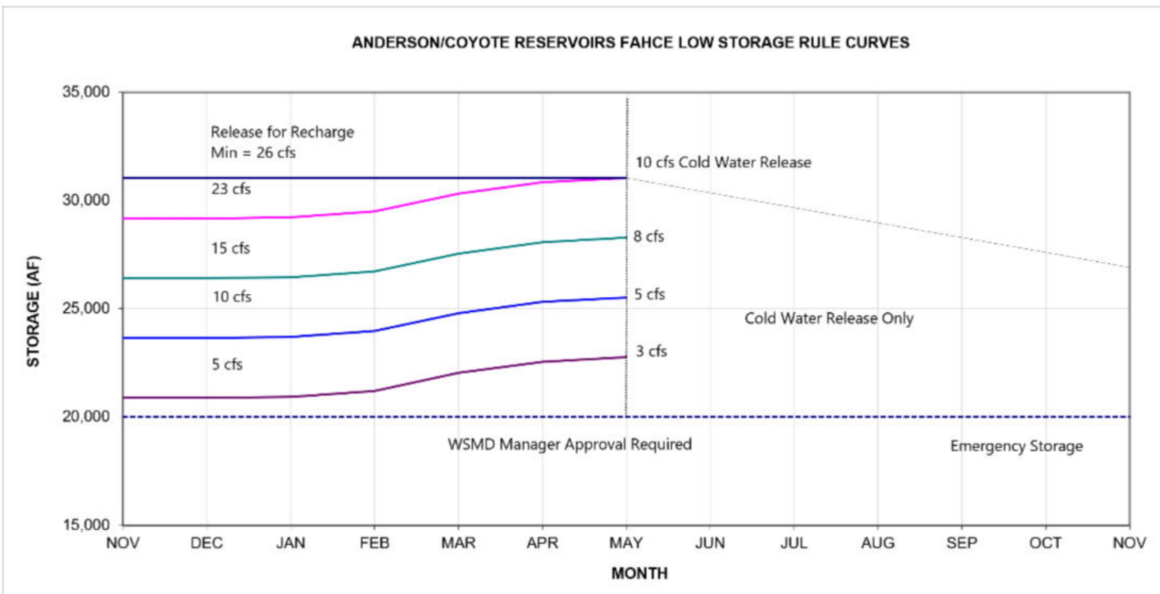

Table 2-19~~2-20~~. Combined Anderson Reservoir and Coyote Reservoir Storage Thresholds (AF) for Winter Base Flow Releases (CFS) Under FAHCE Rule Curves

Begin Month Combined Storage (AF)	Min. Base Flow Release 26 cfs	Min. Base Flow Release 23 cfs	Min. Base Flow Release 15 cfs	Min. Base Flow Release 10 cfs	Min. Base Flow Release 5 cfs
November 1	31,050	29,173	26,411	23,648	20,886
December 1	31,050	29,173	26,411	23,648	20,886
January 1	31,050	29,216	26,454	23,691	20,929
February 1	31,050	29,495	26,733	23,970	21,208
March 1	31,050	30,316	27,554	24,791	22,029
April 1	31,050	30,842	28,080	25,317	22,555
May 1	31,050	31,050	28,288	25,525	22,763

As shown in **Figure 2-13** and **Table 2-19**, proposed winter flow releases would not be initiated until there is adequate storage above a given curve to allow for five days of consecutive releases at that release rate. The maximum flow release rule curve criterion for Anderson Reservoir is 23 cfs. However, if the storage is above the highest winter base rule curve, then 26 cfs or the flow rate that is required for aquifer recharge will be released[26]. As reservoir storage decreases, or if storage never reaches the maximum reoperation rule curve, a reduced winter base flow would be released as described in **Figure 2-13** and **Table 2-19**. In dry water years, where adequate storage above even the minimum rule curve does not allow for 5 days of consecutive releases, winter base flow releases may not occur. In addition to following FAHCE Rule Curves, Valley Water's releases must also meet the minimum bypass flow releases that are required by LSAAs at all instream diversions below Anderson Dam to maintain a wetted channel downstream of facilities when water is being diverted. The specific flow rate would depend on reservoir storage and where storage volume falls within the range of the graduated curves.

Incidental flood risk reduction releases may also contribute to winter base flows by releasing up to 1,485 cfs through the LLOW. The incidental flood risk reduction releases are releases that under Pre-FERC Order conditions would have likely been lost through an uncontrolled spill event. After completion of the Project, reservoir storage will be increased and the LLOW would be capable of releasing larger volumes of water, enabling Valley Water more flexibility to make incidental flood risk reduction releases, and the recurrence of spillway events is likely to decrease.

2.8.3.2 Proposed Spring Pulse Flow Releases

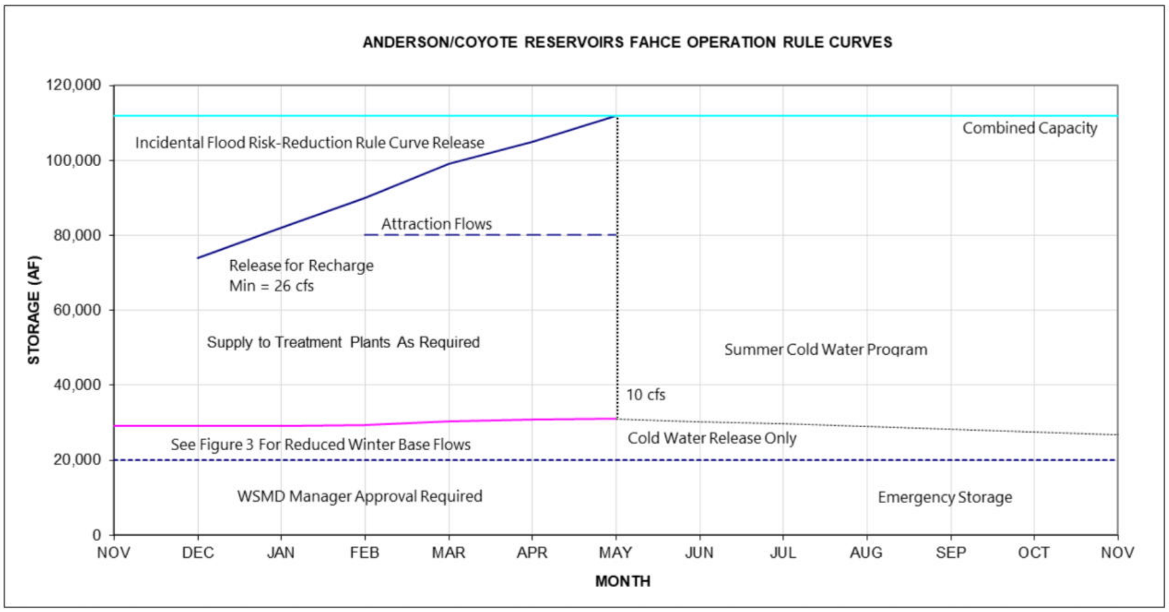
When reservoir storage allows, Valley Water would implement up to 2 pulse flows between December 1 and April 1 (inclusive) to improve passage conditions for migrating salmonids. When the combined reservoir storage of Anderson and Coyote exceeds 80,000 AF, up to two

[26] Recharge releases are generally determined by achieving 2.5 cfs of streamflow at station 5058, Coyote Creek at Edenvale.

pulse flow events would be triggered (**Figure 2-14**). Pulse flows are reservoir releases of 50 cfs for a period of 5 consecutive days made between February 1 and April 30, as measured at Stream Gage 5082 (Coyote Creek at Madrone). These flows are intended to enhance upstream passage for adult steelhead, by providing attraction flows and improving passage conditions. These events would also benefit out-migrating juvenile steelhead and Chinook salmon by flushing them downstream from the upper watershed, aiding them in their migration to San Francisco Bay, and ultimately, to the ocean.

Reservoir storage levels that would trigger spring pulse flows are probable in average to wet water years, or about 50 percent of the time. Anderson Reservoir would be operated in this manner until there have been two periods of 5 consecutive days of flows greater than 50 cfs in the current water year. Flood flow releases and spill events in excess of 50 cfs for 5 consecutive days between February 1 and April 30 would also be considered pulse flow events.

Figure 2-14. Anderson-Coyote Combined Reservoirs Operation Rule Curves: FAHCE Pulse Flows



2.8.3.3 Proposed Summer Cold Water Flow Releases

Summer flow releases from Anderson Reservoir would be made between May 1 and October 31 at a rate sufficient to maintain a continuous flow of water with a temperature not to exceed a daily average of 18°C ~~or less~~ in the FCWMZ and a minimum flow of 1 cfs at the downstream end of the FCWMZ. When the Ogier Pond CM been completed, Valley Water will shift the temperature and flow objectives to maintain a continuous flow of water with a temperature not to exceed a daily average of 18° C~~or less~~ and a minimum flow of 1 cfs at the downstream end of as much of the entire CWMZ as feasible based on available cold water storage. If there is not sufficient storage to satisfy this condition, the daily release rate will be equal to the total available cold water storage less estimated evaporation divided by 184 days (i.e. the time period from May 1 through October 31). Reservoir storage in excess of the minimum recharge curve may be released to Coyote Creek or sent to the Raw Water Distribution System.

In dry or very dry years, imported water may be used to supplement Anderson reservoir releases for groundwater recharge, and incidentally to provide summer rearing habitat benefits. If ~~if~~ imported water is released for cold water management, then releases of imported water, together with any concurrent releases of Anderson Reservoir, shall not exceed 57.2°F (14°C). As noted above, any use of imported water in lieu of local supply from Anderson Reservoir would result in the reclassification of an equivalent volume of local water in Anderson Reservoir from local water to imported water for the purpose of applying the Reservoir Reoperation Rule Curves.

Below Anderson Dam, Valley Water would maintain Coyote Creek FCWMZ, and, after completion of the Ogier Ponds CM, the CWMZ to provide over-summer refugia for rearing steelhead based on available cold water in Anderson Reservoir. The extent of the CWMZ may vary by year, depending on Anderson Reservoir storage volume and local precipitation and inflows. Between April 15 and April 30 of each year, Valley Water would perform a thermal profile survey of Anderson Reservoir to determine the volume of the hypolimnion that is at or below 57.2°F (14°C) using ~~). Based on this information, Valley Water would determine~~ the depth to cold water and a rating curve to calculate the size of the cold water pool in AF. The ~~appropriate~~ reservoir release rate from May 1 ~~rates to maximize the extent of the CWMZ~~ through October 31 would be equal to or less than the total available cold water storage in AF, less the estimated evaporation divided by 184 days.[27] If required, additional reservoir temperature profiles may be made monthly from June through October to aid in determining cold water releases. Additional imported water may be introduced to Anderson Reservoir at any time, so long as the water is introduced in a manner that does not jeopardize the volume of the hypolimnion that is at or below 57.2°F (14°C).

2.8.3.4 Proposed Flow Ramping

Flow ramping is used to manage changes in flow volumes of each type of release (winter base flow, pulse flow, and summer cold water program release) to minimize impacts on aquatic species. Flow ramping manages changes in the rate of water flow in a slow, stepwise fashion, helping fish and other aquatic life to avoid stranding. Ramping would occur whenever Valley Water-controlled flows would be ~~increased or~~ decreased by 50 percent or more from the existing flow condition.

Flows that are under Valley Water control would be reduced in specified increments over a specific period of time, in accordance with the discharge rating curves that would be used to determine ramping schedules. Ramping would be applied to reservoir releases, pulse flow releases, and controlled releases from pipelines and diversion dams. Flow ramping applies only to flows within Valley Water control; inflow to the stream from uncontrolled events such as natural runoff or reservoir spillway flows is not subject to the ramping provisions.

When ramping is needed, Valley Water would implement protocols to ramp reservoir releases, depending on whether the original flow is more or less than 50 cfs.

[27] Typically, Anderson Reservoir releases allowed for by the available cold water pool are managed to maintain the temperature in the Coyote Creek FCWMZ ~~is maintained~~ such that the daily average temperature does not exceed 18°C. Water temperatures may also be augmented with releases from the CVP or SCC, as necessary, Coyote Discharge Line. Imported releases (together with any concurrent Anderson Reservoir releases) made between May 1 through October 31 shall not exceed 14°C at the CDL Outlet.

2.8.4 Imported Water Storage and Releases

As noted above, Anderson Reservoir operations would allow for the storage of imported water from the SCC, the Cross Valley Pipeline and/or San Luis Reservoir in Anderson Reservoir, if available, in late winter and spring, while temperatures of imported water is still relatively cold and so long as water can be released to the reservoir without jeopardizing the maintenance of the reservoir cold pool storge. This would enable Anderson Reservoir to increase in depth, thereby increasing the cold-water volume in the reservoir. In addition, imported water may be released into Anderson Reservoir at other times of the year, if necessary, to avoid losing Valley Water supplies stored in San Luis Reservoir, or in anticipation of a planned shutdown in the conveyance system from San Luis Reservoir to Santa Clara County, or to otherwise preserve the cold water pool and/or summer releases, so long as water is introduced into the reservoir in a manner that does not jeopardize the volume of the hypolimnion that is at or below 57.2°F (14°C).[28]

Santa Clara Conduit and Cross Valley Pipeline releases to Coyote Creek (via the CDL) may be made anytime from November 1 through April 30. ~~;~~ Releases ~~releases~~ may also be made from May 1 through October 31 ~~so long as the temperature with any Anderson Reservoir water of the imported water~~ if releases from the CDL cannot occur because water temperature exceeds ~~released is~~ 14°C or ~~less at the CDL outlet.~~ if stream flow from Anderson Dam does not reach the Cross Valley Pipeline Extension outfall and a dryback is present downstream. In dry and severely dry years when releases from Anderson reservoir and/or the CDL are not sufficient to prevent dryback in the vicinity of the Cross Valley Pipeline ~~CVPE~~ outlet, Cross Valley Pipeline ~~CVPE~~ release may be made to manage groundwater recharge, attempt to meet minimum LSAA flow targets downstream of Coyote Percolation Ponds and at Edenvale, and support fisheries, wetland and riparian habitat types. Valley Water would release imported water to the downstream end of the CWMZ via the Cross Valley Pipeline Extension. If stream flow from Anderson Dam does not reach the Cross Valley Pipeline Extension outfall and a dryback is present downstream of the outfall, Valley Water may release imported water to Coyote Creek from the Cross Valley Pipeline Extension for managed groundwater recharge and to maintain a wetted channel downstream of the release point with no temperature limitation.

2.8.5 Anderson Dam and Pipeline Facilities Maintenance

Maintenance of dam appurtenances is necessary to ensure the safe and efficient working of Anderson Dam over time. Valley Water would maintain the newly retrofitted Anderson Dam as part of Valley Water's DMP and PMP.

2.8.5.1 Dam Maintenance Program

The DMP includes over 65 covered maintenance activities within each dam's Area of Routine Maintenance Effects (ARME)[29] (Valley Water 2007). These DMP maintenance activities have

[28] Valley Water's stored supplies at San Luis Reservoir are subjected to DWR and Reclamation rules and approval, and Valley Water's stored supplies may not interfere with operations of the projects. For example, stored supplies may be lost to make room for SWP and CVP Project ~~project~~ supplies at San Luis Reservoir when Project ~~project~~ storage becomes limited.

[29] The ARME describes the areas where activities will occur on a regular basis. The ARME includes areas of routine work and a corresponding buffer defined by Valley Water engineers and maintenance personnel. Routine maintenance includes activities such as road repair, bank

been grouped into four major categories outlined below and include both routine and corrective maintenance. Routine (preventive) maintenance consists of normal work performed to existing infrastructure to maintain the expected life cycle of the appurtenance. Corrective maintenance consists of the replacement of components or appurtenances that have failed to maintain the service of the infrastructure.

The following categories of DMP maintenance would apply to the Project seismic retrofit improvements, and would be implemented pursuant to DMP AMMs:

- Surfaces and/or Earth Work – any work on the natural environment at the ground surface level
  - Vegetation management
  - Burrowing rodent control
  - Access road and boat ramp work
  - Erosion control/bank stabilization/drainage
  - Embankment repair (cracking and slumping)
  - Trash and debris removal
- Maintenance of Dam Appurtenances and Equipment – any work on dam equipment, mechanical equipment, monitoring instruments, or supervisory control and data acquisition systems.
  - Inlets/outlets
  - Valve systems and hydraulic systems
  - Sediment removal around intake structures and hydraulic lines
  - Concrete structure repairs, Replacement and Cleaning (including weep holes)
  - Seepage systems (weirs and piping)
  - Other appurtenances (piezometers, electrical systems, fences, etc.)
- Inspections, Monitoring, and Exploratory Work – ongoing inspections to enhance the lifetime of the infrastructure
  - Exploratory field investigations (including exploratory drilling on land and from barges)
  - DSOD and other inspections
- Reservoir Dewatering – activities to provide access to and refurbish dam appurtenances located in wetted areas

Routine maintenance that would be required for the newly constructed Anderson Dam infrastructure is summarized in **Table 2-25.**

stabilization at the base of the spillways, rodent control, and equipment maintenance, which could happen every year or every few years. Approximately 85 percent of impacts would occur within the ARME. Some less frequent impacts could occur outside the ARME but within the larger APE. These impacts are estimated to be about 15 percent of the total impacts from the Project.

2.8.5.2 Pipeline Maintenance Program

The PMP addresses maintenance for several pipelines and pipeline facilities Valley Water owns and/or maintains (Valley Water, 2007). The program establishes a process for conducting routine water conveyance system maintenance activities including maintenance on pipelines, pump stations, blow offs, turnouts and vaults. Routine maintenance activities covered under the PMP include:

- Cathodic protection and monitoring
- Leak repair
- Internal pipe inspection
- Unscheduled releases of water due to pressure surge
- Rehabilitation and/or replacement of pipeline components
- Bank stabilization and erosion control related to pipeline infrastructure
- Replacement and repair of buried service valves
- Maintenance of pipeline turnouts
- Replacement/repair of appurtenances, fittings, manholes and meters
- Vault maintenance
- Telemetry cable/system inspections and repairs
- Maintenance of pump stations, operations yards, utility yards and corporation yards
- Access road repairs

Routine maintenance that would be required for the newly constructed Anderson Dam facilities and pipeline infrastructure is summarized in **Table 2-20** ~~Table 2-21~~.

Table 2-20 ~~2-21~~. Summary of Proposed Anderson Reservoir Maintenance Activities

Project Component	Maintenance Activities
Dam Embankment[1]	Maintenance activities for the dam embankments include rodent control, vegetation maintenance (includes cut stump method), instrumentation maintenance, concrete slab repair, exploratory drilling, embankment repairs, access road maintenance, and erosion control and repair.
Spillway[1]	Maintenance activities for the spillway include routine maintenance of the debris boom, repair, and replacement of any broken parts of the debris boom, replacement of the debris boom every 10 years, drainage maintenance (includes cleaning the drainage system, vegetation maintenance, soil and debris removal behind the spillway walls, maintenance of access points and roads). Drainpipes and weepholes would also be regularly cleaned out to ensure proper drainage from behind the spillway walls.
Inlet/Outlet Works[1]	Maintenance activities would include inspection, repair, and replacement of steel liners and pipe, concrete repairs, and removing sediment/stabilizing slopes around inlet structures and hydraulic/control lines. Repair and replacement of fencing and signage, access points and roads, lighting, and security features would also be performed. ~~Valley Water's contractor would provide security to minimize the potential for theft from the construction site.~~ Excess vegetation and sediment would be periodically removed from the spillway to prevent blockages and maintain positive drainage. Inspections of the valves would be required every 10 years. Routine annual valve exercises would also be conducted. The valve exercise would consist of inspection and observations of the valve conditions, fully opening and closing the valves, and repair and replacement of any broken parts. The HLOW would be normally operated, with the portion of the 13-foot tunnel downstream of the 13-foot wheel gate empty and the 11-foot fixed cone valves open.
Anderson Force Main and Main Avenue Pipelines[2]	Realignment and connections of the underground Anderson Force Main and Main Avenue Pipelines would be maintained in a manner consistent with the existing Valley Water PMP. Valves and appurtenances at the LLOW would be maintained as part of the DMP, which would include routine inspections, annual tests, and monitoring. The Anderson Force Main and Main Avenue Pipelines would be maintained in accordance with the PMP, which includes scheduled maintenance, inspections, and periodic dewatering. Pipeline dewatering of these pipe sections would be achieved though releasing water into Coyote Creek via the LLOW (Valley Water 2007, 2012).
Temporary and Permanent Roadway Modifications	Earthen roads would be maintained annually by re-grading the surface and importing materials to ensure a safe travelling surface. Paved roads would be maintained annually to keep cracks sealed, remove potholes, and resurface roadways, as needed. Re-paving would be done every 10-15 years. Repainting and repaving of the recreational parking areas would be maintained by County Parks.

Project Component	Maintenance Activities
Recreational Facility Modifications	After the completion of park restoration, County Parks will assume maintenance and operation of all recreational facilities. Valley Water will continue to maintain restoration sites adjacent to recreational areas, which would include tree irrigation, maintenance of replaced trees, maintenance of fencing around Valley Water facilities, sediment augmentation, and potentially replacing the installed large woody debris structures that would be placed in Coyote Creek for fish habitat enhancement.
Decommissioning of Hydroelectric Facility	The facility would not be used once it is decommissioned. However, standard building maintenance would be required to prevent the building from deteriorating. Routine building maintenance such as vegetation management, inspections, building and fencing repair, trash removal, and maintenance of signage would be conducted to upkeep the building.

Notes:

[1.] The DMP describes routine maintenance associated with the Dam Embankment, Spillway, and Outlet Works.

[2.] The PMP describes routine maintenance associated Anderson Force Main and Main Avenue Pipelines.

Key: DMP = Dam Maintenance Program; HLOW = high-level outlet works; LLOW = low-level outlet works; PMP = Pipeline Maintenance Program

2.9 Post-Construction Conservation Measures Operations and Maintenance

Following construction, ongoing compliance monitoring would confirm the functionality and success of conservation measures, and guide long-term operation and maintenance of CMs. In many cases, adaptive management of CMs would overlap with the long-term operation of CMs. As described above in **Table 2-1** and below in Section 2.10, post-construction adaptive management of ADSRP CMs would be implemented as a part of ADSRP based upon the adaptive management framework already established by the FAHCE program, including Vally Water's ~~VW's~~ determination of specific adaptive management actions in coordination with the AMT . Post-construction maintenance activities would be performed in accordance with applicable provisions of the Valley Water Stream Maintenance Program (SMP) as described in this section below. ~~Post-construction operations and maintenance of the Anderson Dam Facilities and Conservation Measures, as well as FAHCE Adaptive Management, is not anticipated to utilize any new natural gas in buildings or install any new non-EV charging spaces for maintenance employees.~~

2.9.1 CDL and Cross Valley Pipeline Extension Pipeline Maintenance for Imported Water and Dam Releases

CDL and Cross Valley Pipeline Extension pipeline maintenance would be the same as that described in Section 2.8.5 above for Anderson Dam related pipelines, and would be conducted under Valley Water's PMP (2007).

2.9.2 Ogier Ponds Operations and Maintenance

2.9.2.1 Maintenance

Although the low-flow channel and floodplain would be designed to be geomorphically stable, following the restoration of creek flows to the pre-1997 channel, Valley Water would maintain the restored channel, including its berms, to support flow capacities. In addition, Valley Water ~~water~~ would maintain spillway structures/fish screens between the restored channel and the remaining ponds to support proper functioning of the ponds and protect the restored channel from high flow events. Valley Water would also conduct maintenance of access roads to ensure site access. Maintenance roads would be located along the new creek channel on the southwest left bank of Coyote Creek.

Ongoing vegetation and sediment removal from the channel, as necessary, would ensure that the channel maintains adequate flow capacity to meet the goals of the Project. This would include vegetation management that would remove vegetation and sediment that restrict flows in the creek channel beyond Project design goals, invasive plants that compete with native plants and detract from the ecology of the creek habitat, trimming and/or removal of vegetation, and replanting or other efforts to establish native vegetation. Berms, spillways, fish screens, in-channel bio-engineered habitat enhancements (e.g., root wads, stream barbs, overhanging banks), rock slope protection, and stormwater outfalls would also need to be inspected and repaired, as necessary. Maintenance of the spillway and fish screens would be conducted by Valley Water. Additional maintenance activities would include trash removal, inspections of infrastructure to identify maintenance issues, and access and maintenance road inspections. County Parks would maintain recreational facilities, such as trails, picnic areas, access and parking areas, dog-training area, and a controlled model airplane field. Channel maintenance would be performed through the Valley Water SMP. Vegetation management required to maintain the ponds and recreational facilities would be conducted by County Parks.

2.9.2.2 Operations

Operations for Ogier Ponds involve allowing creek flows to flow through the pond only in certain circumstances. The spillway structure would be designed to divert flows from the restored channel to the ponds to protect the integrity of the channel when flows exceed 2,000 cfs. The culvert and fish screens re-connecting flows from the downstream pond with the restored channel would similarly be maintained and operated to allow flows to reenter the creek when flows exceeding 2,000 cfs enter the ponds. Eliminating creek flow through the ponds under general conditions via the creek pond separation projects is a key element of improving summer temperatures and reducing predation within the Ogier Ponds Reach of Coyote Creek for the benefit of steelhead. As part of the Ogier Ponds CM, the creek channel would be widened and separated from ponds that remain after creek/pond separation by weir and berms. Water would be generally maintained in ponds by groundwater seepage. Changes in water quality that may occur due to creek channel/pond separation as necessary to improve temperature and other steelhead habitat conditions within Coyote Creek include ~~:~~ reduction in DO (particularly in summer time) and surface water changes. Creek flows through the ponds would only occur via operation of spillway. The spillway structure would be designed to divert flows to ponds when creek flows exceed 2,000 cfs, to help protect the integrity of the creek channel banks/berms. High flows would flow into Pond 2 through spillway, then travel through Ponds 3 and 4, until flows exit Pond 4 and flow back into the creek via a culvert that will have fish screens to prevent predation. Monthly inspections would be conducted to monitor water quality changes. To maintain or improve DO in the ponds during normal conditions in the absence of creek flow-through, solar powered floating aerators would be installed to maintain or improve DO as compared to existing conditions. Other water quality best management practices may also be deployed, if necessary, as indicated by pond water quality monitoring results to maintain or improve upon existing water quality conditions in the ponds.

2.9.3 North Channel Reach ~~Extension~~

Long term maintenance of the North Channel Reach, which includes the maintenance activities discussed in this section below, would be conducted under the SMP for the North Channel and in accordance with the DMP (2012) for the weirs.

2.9.3.1 Maintenance

Following large flow events, including releases from the spillway, Valley Water would monitor the North Channel to ensure that the channel maintains a positive draining channel, and that debris is not accumulating within the channel. If channel conditions were negatively impacted by a large flow event, the North Channel would be inspected to determine the required actions necessary to restore the flow capacity of the channel. This may include debris and/or vegetation removal from the channel or, if regrading is required, further dewatering of the channel to provide a dry area where the regrading of the channel bottom may occur to maintain a positive draining channel. The channel would also be assessed to ensure that large pools or irregular backwaters are not forming that could result in fish strandings as waters recede within the North Channel. The wetland bench would also be inspected following large flow events, and replanting and/or repairs would be implemented, as needed.

2.9.3.2 Operations

The ~~Post construction operation of the~~ North Channel ~~Extension would involve the same operations described in Section 2.6.2. The north channel~~ weir design includes a labyrinth weir that would activate the rock-lined north channel when post-construction releases from the reservoir exceed approximately 100 ~~230~~ cfs. The weir at the head of the southern channel includes a 5-ft-wide ‘U’ shaped channel invert weir, with slots on which stop logs may be installed. The stop logs create a variable weir system that would be installed on the south weir. This ~~, this~~ would allow the North Channel ~~north channel~~ to be activated when reservoir releases exceed 100 cfs~~, rather than 230 cfs~~. High flows would be managed between the channels using the labyrinth weirs to direct flows of up to 230 cfs through the South Channel, and flows greater than 230 cfs through the restored North Channel, limiting flows within the South Channel. This would minimize the potential for erosion and support salmonid spawning within the South Channel, while minimizing fish stranding throughout the restored North Channel where deep holes would be graded out~~, and facilitate access for channel maintenance. The grading of the North Channel alignment would also eliminate the existing deep pools throughout this reach that otherwise may result in fish stranding as water recedes after high flow events.~~.

2.9.4 Sediment Augmentation Program Maintenance ~~Operations~~

During post construction as a part of the implementation of the Project and FAHCE AMP, following ~~Following~~ large flow events and in response to post-construction incision, deposition, and spawning and rearing habitat monitoring data and information, Valley Water would inspect habitat quality within the CWMZ, focusing on, but not limited to, the Live Oak Restoration Reach and the Ogier Ponds Restoration Reach sites, to determine if habitat maintenance is required. Activities and locations for habitat enhancement via sediment augmentation would be determined pursuant to the Project adaptive management program described in Section 2.10. Maintenance would include placing up to 500 cy of ~~spawning gravels or~~ sediments in multiple locations within the Live Oak Restoration Reach ~~Coyote Creek between Anderson Dam~~ or ~~and~~ Ogier Ponds Restoration Reach every 5 years, as and where determined to be necessary pursuant to the Project adaptive management program described in Section 2.10. Culverts and low flow crossings between the dam and Coyote Percolation Ponds would also be inspected and maintained after dam releases that exceed 500 cfs to assure that habitat enhancement via the sediment augmentation program does not impair channel capacity or hydraulics.

Post construction maintenance ~~operation~~ of the Sediment Augmentation Program would involve the same methods and activities described in Section 2.6.3 though quantity and placement of sediment, gravels and woody debris within the CWMZ may vary in response to monitoring data. Maintenance of culverts and low-flow crossings would include excavating sediments that have filled or blocked culverts or crossings using hand tools or heavy equipment (bobcat or small excavator).

2.9.5 Phase 2 Coyote Percolation Dam Operations and Maintenance

2.9.5.1 Maintenance

After completion of the roughened channel as a part of the Phase 2 Coyote Percolation Dam design and restoration of flows within Coyote Creek, ongoing maintenance would be necessary to ensure that groundwater recharge capacity, fish passage criteria and roughened channel flow capacity are maintained over time. Maintenance activities would include the periodic removal of sediment deposited in the restored channel when it could compromise the channel's conveyance capacity, results in geomorphic instability, or is detrimental to the quality of aquatic habitat. Additional maintenance would be required at Coyote Percolation Dam because injected sediments introduced to the CWMZ as a part of the Sediment Augmentation Program are expected to deposit in the percolation ponds and may potentially also be depositing in the channel, particularly upstream of the facility. This maintenance work would be done using hand tools or heavy equipment (bobcat, small excavators). Vegetation management would also be required. Vegetation management activities would include the removal of invasive plants and trimming and/or removal of growth clogging the channel. Vegetation management would occur on a routine basis. The crew would consist of two to four maintenance staff. Maintenance staff would also inspect the roughened channel bi-annually, particularly after large flows, and replace roughness elements and/or repair in-channel bio-engineered habitat enhancements (e.g., root wads, stream barbs, overhanging banks), and enhance rock slope protection, as needed, to maintain channel function and fish passage conditions. Similar to the Anderson Dam facilities, the Coyote Percolation Dam CM would be covered under Valley Water's DMP (2012).

2.9.5.2 Operations

Consistent with current operational rules of the Coyote Percolation bladder dam, installed as a part of FOCP to allow more flexible operations for the benefit of steelhead than are possible with a flashboard dam, the bladder dam would be lowered during high flow events (exceeding approximately 250 ~~320~~ cfs) and then be raised after high flow events have receded. The facility would pass flows up to 250 ~~320~~ cfs via a combination of the fish ladder and radial gates. When flows are predicted to exceed 250 ~~320~~ cfs, releases would be made from the percolation pond via the overshot weir to reduce storage and then deflate the dam when safe to do so. The purpose of draining the pond prior to deflating the dam is to avoid sending a large uncontrolled surge of water down Coyote Creek. When the dam is deflated, all water would be directed over the dam sill with a portion (at least 10 percent of total flow) going through the roughened channel to provide fish passage ~~the radial gates would be closed to direct all water through the fish 26 ladder and over the dam sill to provide fish passage~~. The dam would be inflated when flows recede and can be safely passed via a bypass (overshot weir) ~~the radial gates~~ and fish ladder. The dam and facilities will be designed in accordance with NMFS and CDFW fish passage criteria to safely provide up and downstream passage for flows between 7.5 and 1,320 cfs ~~pass fish during all flow conditions~~. Passage criteria do not apply above 1,320 cfs.

Within 13 months of completion of the Phase 2 Coyote Percolation Dam design (completion of design anticipated prior to ~~in~~ Year 1 ~~4~~), Valley Water will prepare in coordination with the regulatory agencies a Phase 2 Coyote Percolation Dam Operations Plan. The objectives of the Operations Plan will be to continue to provide sufficient groundwater recharge, while improving conditions for smolt migration. Key elements of operations will include the following:

- Operational flexibility to temporarily drain the Coyote Percolation Pond to improve smolt migration when logistically practicable given water supply demands and ecologically appropriate in terms of habitat management to protect steelhead and other listed and sensitive aquatic and riparian species.
- Upstream passage through the Coyote Creek Percolation Dam Facility will be provided at flows between 2.5 cfs and 1,320 ~~320~~ cfs.
- Between October 16th and June 14th, the bladder dam will be inflated when Coyote Creek flows arriving at the dam are less than 275 cfs to facilitate upstream passage through the fish ladder.
  - When the dam is inflated, fish ladder flows will be maintained between 2.5 and 25 cfs, and flows above 25 cfs (and less than 275 cfs) will be released through the new overshot weir ~~bypass gates~~ replacing one of the existing radial gates.
  - The bladder dam will be deflated when Coyote Creek flows arriving at the dam are greater than 275 cfs and upstream passage will be provided by the roughened channel. When the dam is deflated, Coyote Creek flow greater than 275 cfs arriving at the dam will go over the deflated dam, a portion of this flow will go into the roughened channel to provide upstream passage, and under normal operating conditions, the Fish Ladder and bypass gates will be closed.
- During summer periods (June 15th through October 15th) outside of the steelhead migration season, the weir gates in the fish ladder may be raised to cut off flows to the fish ladder and allow inspection and maintenance activities to be conducted. VW will maintain the minimum required flows per the LSAA to Coyote Creek.
- The plan will include an evaluation of smolt migration conditions through the pond under Pre-FERC Order baseline conditions (including dam operations and instream flows) and will include measures to ensure an improvement in migration conditions through the percolation pond as compared to that baseline condition following implementation of Phase 2 designs, including water depth, velocity, and predation risk.

2.9.6 Maintenance Activities at the Live Oak Restoration Reach

In response to long-term habitat assessment monitoring data, the habitat restoration and sediment augmentation activities necessary to maintain the spawning and rearing habitat created at the Live Oak Restoration Reach would continue after construction is completed and in long-term as described for the Sediment Augmentation Program in Section 2.9.4. These activities would include replenishment of spawning gravels in the south channel. The maintenance activities would be accomplished by placing up to 500 cy of gravel in various locations within the CWMZ every 5 years. If high flows are not experienced in the Live Oak Reach, the spawning gravels may stay in place and require only minor additions, in which case the remaining sediment would be used to augment other locations within the CWMZ where indicated to be appropriate by monitoring information. Maintenance of installed wood structures would require replacing structures and associated hardware if they appear to be creating hazardous conditions within Live Oak Park.

Activities and methods to implement ongoing maintenance of the Live Oak Restoration Reach spawning and rearing habitat are the same as those described for the Sediment Augmentation Program Section 2.6.3.

In the long-term Live Oak Maintenance via the Sediment Augmentation Program would be adaptively managed. The long-term, post-construction adaptive management of the Live Oak Restoration Reach would occur in accordance with the Sediment Augmentation Program and would be implemented in the same manner pursuant the framework established by the FAHCE Program, as described in that program and in Section 2.10.

2.10 Project and FAHCE Adaptive Management Program

The FAHCE AMP, outlined in Chapter 6 of the FHRP in accordance with the FAHCE *Settlement Agreement* (2003), would guide post-construction adaptive management of Project flow operations, and all non-flow fish barrier remediation and habitat restoration Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. A Project-specific AMP (see Appendix D for details) has been developed in accordance with the framework described in the FAHCE Settlement Agreement and FAHCE Program. Implementation of the Project and FAHCE AMP is designed to satisfy the ~~measurable objectives defined in the~~ FAHCE Settlement Agreement and ~~the~~ FAHCE Program commitment and overall conservation objective to restore and maintain a healthy steelhead trout and salmon population in the Coyote Creek watershed, by providing: (A) suitable spawning and rearing habitat within Coyote Creek (consisting of approximately five miles of spawning and rearing habitat below Anderson Dam and in Upper Penitencia Creek); and (B) adequate passage for adult steelhead trout and salmon to reach suitable spawning and rearing habitat and for out-migration of juveniles. The measurable objectives are designed ~~FHRP~~, and to assure the long-term management and effectiveness of Project CMs to benefit steelhead and Chinook salmon as defined by the FAHCE Program commitment.

The FAHCE AMP component of the Project and FAHCE AMP, found in Chapter 6 of the FHRP, would guide adaptive management of all post-construction dam facility (FAHCE rule curve) operations, and long-term configuration and operation of all non-flow fish barrier remediation and habitat restoration Conservation Measures (i.e., Maintenance Activities at the Live Oak Reach Restoration, Ogier Ponds CM, and Phase 2 Coyote Percolation Dam CM). As in the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements:

Measurable Objectives. The FAHCE *Settlement Agreement* (2003) and the FHRP provide measurable objectives for steelhead and salmon fisheries and their habitats. These objectives would be achieved through implementation of FAHCE flow and non-flow measures for Coyote Creek, along with implementation of additional conservation measures identified in this Project description (Appendix D).

Monitoring. Monitoring activities would focus on compliance, validation, effectiveness and long-term trends. Systematic monitoring would be conducted of actual habitat conditions affected by the post-construction operations flow measures and non-flow conservation measures implemented under the FAHCE, FOCP, and Project to determine whether the conservation measures are contributing to the achievement of measurable objectives, and therefore to attainment of the FAHCE Program overall restoration objective. Monitoring activities would evaluate the performance of the entire program in improving habitat quality and availability for steelhead and salmon, as well as the performance in each phase of the program in reducing or eliminating limiting factors affecting various life stages of steelhead and salmon, where such conditions are directly attributable to Valley Water facilities and operations in Coyote Creek.

Adaptive Actions. The Project and FAHCE AMT, including NMFS, other regulatory agencies, and non-governmental organizations (NGOs), would review potential adaptive actions described in the Project component of the Project and FAHCE AMP set forth in Appendix D and prioritize these actions for implementation. This may include modification of post-construction operations flow measures and non-flow conservation measures identified under FAHCE and in this EIR, as well as individual regulatory agency requirements, as appropriate, to help achieve measurable objectives.

Reporting. The AMT would synthesize and analyze results, evaluate progress attained by flow and non-flow measures, and identify potential adaptive actions where needed.

Pursuant to the FAHCE Framework, the Project and FAHCE AMP has been developed. The Project and FAHCE AMP is designed to track progress toward achieving the measurable objectives for Coyote Creek outlined above. The monitoring program to inform selection of adaptive management measures to implement in response to management triggers has been organized into three categories, as follows:

- Compliance monitoring includes administrative metrics such as reservoir releases and cold-water pool volume, compliance with the schedule for implementing a particular program element (such as a site-specific passage impediment remediation project), or progress on planning or feasibility studies.
- Validation monitoring includes physical monitoring of instream flows, depth, velocity, water temperatures within the CWMZ and FCWMZ, areas of enhanced habitat, jump height and pool depth for passage impediments, habitat mapping to assess suitability for various life stages of salmonids, validating flow-habitat relationships, and other elements of the program.
- Effectiveness monitoring evaluates the progress made towards the overall restoration objective established for the FAHCE Program by the FAHCE Settlement Agreement, as follows:
  - Stream flow monitoring for Coyote Creek to determine the efficacy of post-construction operations in creating migratory habitat conditions for steelhead and chinook, as well as other native anadromous fish;
  - Water depth monitoring for POIs within Coyote Creek to determine the efficacy of post-construction operations in creating migratory habitat conditions in Coyote Creek;
  - Fish passage monitoring at Coyote Perc Phase 2 facility to determine the efficacy of post-construction operations, the Coyote Perc Phase 2 design, and the Coyote Perc Phase 2 Operations Plan in providing suitable conditions for adult and smolt migration; and
  - Sediment deposition and habitat monitoring for Ogier Reach and Live Oak Reach to determine the effectiveness of the habitat restoration CMs in achieving suitable rearing and spawning habitat goals in those reaches and to inform ongoing maintenance as well as Sediment Augmentation Program replenishment locations, volumes and timing.
- Long-term trend monitoring includes evaluation of ecosystem responses to management actions and/or natural drivers, including monitoring adult salmonid

abundance, juvenile steelhead density, salmonid migration, steelhead genetics,~~,~~ water quality, and species composition.

Compliance, validation ~~Validation~~, effectiveness and long-term trend monitoring would build on existing monitoring infrastructure (e.g., Valley Water's hydrologic monitoring network) and plans, water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, and electrofishing surveys). Valley Water would also collaborate with the NOAA Fisheries Southwest Fisheries Science Center regarding sampling methodologies to ensure that fisheries population status and trends can be established over time.

The Project and FAHCE AMT would play an important role in adaptive management decision making, as described in detail in the FAHCE AMP. Considerations for adaptive management decision making include inter-annual and seasonal variation in hydrologic conditions, other constraints and limiting factors affecting achievement of the overall management objectives, monitoring results of the actual habitat enhancement measures already implemented, opportunities for improving habitat for other fish, wildlife, and plant species, and more generally, the ecological conditions of the watersheds. Data and analysis from compliance, validation, effectiveness, and long-term trend monitoring, evaluated using measurable objectives, would help determine whether refinements need to be made to post-construction operations reservoir releases, fish passage projects or habitat restoration projects carried out as part of the FOCP and Project to incrementally improve instream fisheries habitat conditions.

The post-construction flow Conservation Measure commitments for each habitat restoration and fish barrier remediation Conservation Measure adaptive management goals, measurable objectives, monitoring types, methods and frequency, triggers for potential management actions, and potential management actions to be considered for implementation by Valley Water in coordination with the regulatory agencies of the Project and FAHCE AMT are summarized in Appendix D. Valley Water's Project-specific commitment to implement adaptive management of Conservation Measures supplements its commitment under FAHCE to adaptive management of FAHCE Phase 1 measures. Because Project Conservation Measures (some of which also constitute FAHCE Phase 1 measures) have been refined and further developed at a project specific level in consultation with NMFS and the other regulatory agencies (CDFW, USFWS, SWRCB) to assure avoidance, minimization and offset of Project environmental impacts to steelhead, the AMP for the Project Conservation Measures is more detailed than the program level FAHCE adaptive management program adopted for other Phase 1 measures for Coyote Creek, Guadalupe Creek, or Stevens Creek. The Project and FAHCE AMP assures long-term management of Project Conservation Measures (many of which also constitute FAHCE Phase 1 Measures) to provide long term conservation benefit for steelhead.

While the Project and FAHCE AMP would be implemented pursuant to the adaptive management framework established by the FAHCE Program, the Project and FAHCE ~~FACHE~~ AMP also supplements the FAHCE AMP, which would continue to provide for study, evaluation and selection of future Coyote Creek FAHCE Phase 2 measures, if required, as outlined in the FAHCE *Settlement Agreement* (2003) and FHRP. The FAHCE *Settlement Agreement* contained a menu of potential Phase 2 measures that have not been defined or evaluated for feasibility. Once Phase 1 measures are fully implemented and 10-year monitoring results are analyzed, a determination of whether or not Phase 2 measures (e.g., revised water releases from Anderson to provide for continuous stream flows to approximately Metcalf Road, remediate Priority No. 2 barriers, implement a trap and truck operation to relocate adult steelhead into upper watershed habitat, etc.) are necessary will be discussed through the FAHCE AMP decision making process.

2.11 Avoidance and Minimization Measures

Valley Water would implement a range of standardized measures to avoid or minimize adverse effects on the environment. These are introduced below and summarized in **Table 2-21**, and described in Appendix A.

2.11.1 Best Management Practices

Best management practices (BMPs) are standard practices that prevent, avoid, or minimize potentially adverse effects associated with construction, operations, and maintenance activities. Valley Water routinely incorporates a wide range of BMPs from its *Best Management Practices Handbook* (Valley Water, 2014) into project designs and throughout the implementation of projects. In addition, for work in and near streams, Valley Water would also employ other BMPs included in the *2019–2023 Stream Maintenance Program Manual* (Valley Water 2019; Appendix A), as necessary, to reduce impacts on specific resources; however, SMP BMPs are only applicable to Project activities conducted at or near surface waters in areas downstream of Anderson Dam. The Project would also include the applicable Valley Water BMPs ~~(~~ as well as VHP conditions (and their associated AMMs), as summarized in **Table 2-21** ~~**Table 2-22**~~**.**

Table 2-21 ~~2-22.~~ Relevant BMPs and VHP Conditions

Valley Water SMP[1]/BMP/VHP No.	SMP/BMP/VHP Summary
Aesthetics	
BMPs	
REVEG-1: Seeding	Would require that restored areas are planted with native seeds as soon as work activities are complete
REVEG-2: Planting Material	Would require that restored areas are replanted with locally collected native species and that species selection is based on surveys of natural areas on the same creek that have a similar ecological setting
BI-8: Choose Local Ecotypes of Native Plants and Appropriate Erosion Control Seed Mixes	Would require that restored areas are planted with native species that are ecologically appropriate to the work area and help improve visual conditions post-construction
WQ-11: Maintain Clean Conditions at Work Sites	Would require that work areas and access roads are maintained in an orderly condition and that materials or equipment left on site overnight are stored as inconspicuously as possible
VHP Conditions	
VHP Condition 7	Would reduce impacts of rural development

Valley Water SMP[1]/BMP/VHP No.	SMP/BMP/VHP Summary
Agriculture and Forestry Resources	
BMPs	
AQ-1: Use Dust Control Measures	Would reduce the potential for construction-related dust to damage or reduce the productivity of agricultural activities nearby.
BI-11: Minimize Predator-Attraction	Would reduce the potential for pests to be attracted to the Project Area, causing damage to agricultural operations.
WQ-4: Limit Impacts from Staging and Stockpiling Materials	Would reduce the potential for equipment at staging areas and stockpiled materials to damage soils in agricultural production.
WQ-11: Maintain Clean Conditions at Work Sites	Would reduce the potential for debris to attract pests to the Project Area, causing damage to agricultural operations.
TR-1: Use Suitable Public Safety Measures	Would reduce the potential for safety impacts on traffic.
Air Quality	
BMPs	
AQ-1: Use Dust Control Measures	Would require implementation of dust and air quality management measures, including implementation of BAAQMD's BMPs for dust suppression.
AQ-2: Avoid Stockpiling Odorous Materials	Would avoid stockpiling odorous materials within 1,000 feet of sensitive land uses.
Biological Resources	
BMPs	
AQ-1: Use Dust Control Measures	Would reduce the potential for construction-related dust to damage or reduce the productivity of agricultural activities nearby.[30]
WQ-1: Conduct Work from Top of Bank	Would reduce the effect of machinery on streambed and water quality.
WQ-3: Limit Impact of Pump and Generator Operations and Maintenance	Would reduce impacts to water quality and aquatic species.
WQ-4: Limit Impacts from Staging and Stockpiling Materials	Would reduce runoff and erosion and reduce impacts on instream biota and water quality.

30 Due to the unique and complex nature of Seismic Retrofit Construction, one minor variance from the BAAQMD BMPs related to vehicle speeds on unpaved roads is necessary in certain situations and areas to make it feasible for the Project, as detailed in Section 3.3.3.7, *Applicable Best Management Practices and BAAQMD Measures*. The 15 miles per hour speed limit would apply to all vehicles and equipment only in areas containing naturally occurring asbestos. Outside of these areas, a 25 mile per hour speed limit would be observed for haul trucks on unpaved roads (light duty pick-up trucks would observe the 15 mile per hour limit), such as the in-reservoir access roads to Stockpile Areas K and L.

Valley Water SMP[1]/BMP/VHP No.	SMP/BMP/VHP Summary
WQ-5: Stabilize Construction Entrances and Exits	Would reduce runoff and erosion and reduce impacts on instream biota and water quality.
WQ-6: Limit Impact of Concrete Near Waterways	Would reduce runoff from increasing impervious surfaces and eliminate contact with uncured concrete.
WQ-8: Minimize Hardscape in Bank Protection Design	Would reduce downstream or adjacent bank scour and erosion.
WQ-10: Prevent Scour Downstream of Sediment Removal	Would decrease scour downstream of sediment removal by grading the channel transitions and ensuring that there are no rapid changes in the slope.
WQ-15: Prevent Water Pollution	Would reduce impact to aquatic species and reduce transport of pollution in the channel network.
WQ-16: Prevent Stormwater Pollution	Would prevent stormwater pollution by installing sedimentation and erosion control measures.
BI-3: Remove Temporary Fills	Would remove temporary fill material upon finishing work to reduce impacts to water quality.
BI-4: Minimize Adverse Effects of Pesticides on Non-Target Species	Would limit of use of pesticides.
BI-5: Avoid Impacts to Nesting Migratory Birds	Would protect migratory birds.
BI-6: Avoid Impacts to Nesting Migratory Birds from Pending Construction	Would limit construction to protect migratory birds.
BI-9: Restore Riffle/Pool Configuration of Channel Bottom	Would enhance aquatic habitat and restore its functions to native biota.
BI-10: Avoid Animal En~~t~~ry and Entrapment	Would avoid entrapment of local species.
BI-11: Minimize Predator Attraction	Would reduce the likelihood of predation on native species.
WQ-2: Evaluate Use of Wheel and Track Mounted Vehicle in In-stream Bottoms	Would reduce impacts on instream biota and water quality.
WQ-9: Use Seeding for Erosion Control, Weed Suppression, and Site Improvement	Would reduce erosion and reduce impacts on instream biota and water quality.
~~WQ-12: Manage Well or Exploratory Boring Materials~~	~~Would reduce runoff and erosion and reduce impacts on instream biota and water quality.~~
WQ-11: Maintain Clean Conditions at Work Site	Would reduce impacts related to the storage of construction equipment and materials.
WQ-17: Manage Sanitary and Septic Waste	Would reduce the risk of waste spillage associated with temporary sanitary facilities.

Valley Water SMP[1]/BMP/VHP No.	SMP/BMP/VHP Summary
VEG-1: Minimize Local Erosion Increase from In-channel Vegetation Removal	Would reduce local erosion potential from in-channel vegetation removal.
VEG-2: Non-native Plant Removal	Would reduce impacts from non-native plants in surrounding areas.
VEG-3: Use Appropriate Equipment for In-stream Removal	Would reduce risk of impacts from damaging equipment.
SED-1: Groundwater Management	Would reduce risk of water quality contamination.
SED-2: Prevent Scour	Would reduce impacts on instream biota and water quality.
SED-3: Restore Channel Features	Would restore pre-construction conditions for channel features.
SED-4: Berm Bypass	Would reduce impacts on instream biota and water quality.
REVEG-1: Seeding	Would require that restored areas are planted with native seeds as soon as work activities are complete
REVEG-2: Planting Material	Would require that restored areas are replanted with locally collected native species and that species selection is based on surveys of natural areas on the same creek that have a similar ecological setting
~~HM-7: Vehicle Cleaning~~[31]	~~Would reduce potential impacts associated with cleaning construction vehicles and equipment.~~
HM-8: Vehicle Fuel and Maintenance	Would reduce the risk of spills or accidental releases of hazardous materials.
HM-9: Hazardous Materials Management	Would reduce risk of spills or accidental releases of hazardous materials.
HM-10: Spill Prevention	Would reduce risk of potential spills.
HM-12: Fire Prevention	Would reduce risk of fire and erosion related water quality impacts on instream biota and water quality.
GEN-1: In-Channel Work Window (for maintenance)	Would reduce impacts related to in-channel work.
GEN-4: Minimize Disturbance Area	Would reduce risk area if disturbance area is minimized.
GEN-16: In-Channel Minor Activities	Would reduce large impacts related to in-channel activities
GEN-17: Employee/Contractor Training	Would reduce risk of impacts from improper activities.

[31] BMP HM-7 has been removed in the Final EIR due to conflict with Mitigation Measure HAZ-1, which states that: "Equipment shall be washed down after use and prior to the equipment moving from the work area onto a paved public road. Wheels shall be washed prior to moving equipment from construction areas containing NOA to areas that do not contain NOA."

Valley Water SMP[1]/BMP/VHP No.	SMP/BMP/VHP Summary
GEN-20: Erosion and Sediment Control Measures	Would reduce potential impacts of erosion by installing control measures.
GEN-21: Staging and Stockpiling of Materials	Would reduce impacts related to storing of equipment and materials.
GEN-22: Sediment Transport	Would reduce impacts on instream biota and water quality.
GEN-23: Stream Access	Would reduce number of access points for potential impacts related to increased disturbed areas.
GEN-24: On-Site Hazardous Materials Management	Would reduce risk of potential spills or runoff that may include hazardous materials
GEN-25: Existing Hazardous Materials	Would reduce the risk of impacts from existing hazardous materials
GEN-26: Spill Prevention and Response	Would reduce risk of potential spills of hazardous materials.
GEN-28: Fire Prevention	Would reduce risk of fire impacts.
GEN-30: Vehicle Maintenance	Would ensure that on-site equipment is operating properly through vehicle maintenance.
GEN-31: Vehicle Cleaning	Would ensure that on-site equipment is cleaned away from aquatic resources and sensitive habitats
GEN-32: Vehicle and Equipment Fueling	Would reduce impacts related to fuel spills
GEN-35: Pump/Generator Operations and Maintenance	Would reduce impacts related to pump or generator operations and maintenance.
ANI-5: Slurry Mixture near Waterways	Would reduce potential impacts from slurry
BI-2: Minimize Impacts to Steelhead	Would reduce impacts to Steelhead during activities.
BI-8: Choose Local Ecotypes Of Native Plants and Appropriate Erosion-Control Seed Mixes	Would require that restored areas are planted with native species that are ecologically appropriate to the work area and help improve visual conditions post-construction.
VHP Conditions	
VHP Condition 1	Would reduce impacts to protected plant and wildlife species
VHP Condition 3	Maintain hydrologic conditions and protect water quality
VHP Condition 4	Would reduce impacts for in-stream projects
VHP Condition 5	Would reduce impacts for in-stream operations and maintenance
VHP Condition 7	Would reduce impacts of rural development
VHP Condition 11	Would minimize impacts on streams by specifying setbacks and buffer zones

Valley Water SMP[1]/BMP/VHP No.	SMP/BMP/VHP Summary
VHP Condition 12	Would minimize impacts on wetlands and ponds and avoid impacts on high quality wetlands and ponds
VHP Condition 13	Would minimize or avoid impacts on serpentine soils
VHP Condition 17	Would avoid impacts to Tricolored Blackbirds
VHP Condition 19	Would protect covered plants
VHP Condition 20	Would reduce impacts to covered plants
Cultural Resources	
BMPs	
CU-1: Accidental Discovery of Archaeological Artifacts or Burial Remains	Would formalize response and handling of accidental discovery so as to minimize the potential for disturbing previously recorded or newly discovered prehistoric or historic archaeological resources.
AQ-1: Use Dust Control Measures	Would require implementation of dust and air quality management measures, including implementation of BAAQMD's BMPs for dust suppression.
Energy	
BMPs	
AQ-1: Use Dust Control Measures	Would require implementation of dust and air quality management measures, including implementation of BAAQMD's BMPs for dust suppression.
Geology and Soils	
Handbook BMPs	
GEN-20: Erosion and Sediment Control Measures	Would reduce the potential of erosion by installing control measures.
GEN-21: Staging and Stockpiling of Materials	Would reduce impacts related to storing of equipment and materials.
AQ-1: Use Dust Control Measures	Would require implementation of dust and air quality management measures, including implementation of BAAQMD's BMPs for dust suppression.
BI-3: Remove Temporary Fill	Would reduce the potential for erosion by removing temporary fill.
BI-8: Choose Local Ecotypes of Native Plants and Appropriate Erosion Control Seed Mixes	Would reduce the potential for erosion by planting native plants and installing erosion-control seed mixes.
WQ-4: Limit Impacts from Staging and Stockpiling Materials	Would reduce the potential for equipment at staging areas and stockpiled materials to cause erosion.
WQ-5: Stabilize Construction Entrances	Would reduce runoff and erosion.

Valley Water SMP[1]/BMP/VHP No.	SMP/BMP/VHP Summary
and Exits	
WQ-9: Use Seeding for Erosion Control, Weed Suppression, and Site Improvement	Would reduce the potential for erosion by installing erosion control measures.
BANK-1: Bank Stabilization Design to Prevent Erosion Downstream	Would reduce the potential for erosion at streambanks.
REVEG-1: Seeding	Would require that restored areas are planted with native seeds as soon as work activities are complete
VHP Conditions	
VHP Condition 3	Maintain hydrologic conditions and protect water quality.
VHP Condition 4	Would reduce impacts for in-stream projects
VHP Condition 5	Would reduce impacts for in-stream operations and maintenance
VHP Condition 7	Would reduce impacts of rural development
VHP Condition 8	Would reduce impacts for rural road maintenance
VHP Condition 11	Would minimize impacts on streams by specifying setbacks and buffer zones
VHP Condition 12	Would minimize impacts on wetlands and ponds and avoid impacts on high quality wetlands and ponds
Hazards and Hazardous Materials	
BMPs	
AQ-1: Use Dust Control Measures	Would implement dust and air quality management measures, including implementation of BAAQMD's BMPs for dust suppression.
~~HM-7: Restrict Vehicle and Equipment Cleaning to Appropriate Locations~~	~~Would reduce potential hazardous impacts associated with cleaning construction vehicles and equipment.~~
HM-8: Ensure Proper Vehicle and Equipment Fueling and Maintenance	Would reduce the risk of spills or accidental releases of hazardous materials.
HM-9: Ensure Proper Hazardous Materials Management	Would reduce the risk of spills or accidental releases of hazardous materials
HM-10: Utilize Spill Prevention Measures	Would reduce the risk of spills of hazardous materials.
HM-13: Avoid Impact from Naturally Occurring Asbestos	Would reduce impacts associated with NOA.
WQ-6: Limit Impact of Concrete Near Waterways	Would reduce hazardous impacts related to concrete.
WQ-17: Manage Sanitary and Septic Waste	Would reduce the risk of hazardous waste spillage associated with temporary sanitary facilities.

Valley Water SMP[1]/BMP/VHP No.	SMP/BMP/VHP Summary
TR-1: Use Suitable Public Safety Measures	Would reduce temporary traffic impacts to emergency response providers.
Hydrology	
BMPs	
AQ-1: Use Dust Control Measures	Would reduce the potential for construction-related dust to damage or reduce the productivity of activities nearby.
~~HM-7: Restrict Vehicle and Equipment Cleaning to Appropriate Locations~~	~~Would reduce potential impacts associated with cleaning construction vehicles and equipment.~~
HM-8: Ensure Proper Vehicle and Equipment Fueling and Maintenance	Would reduce the risk of spills or accidental releases of hazardous materials.
HM-9: Ensure Proper Hazardous Materials Management	Would reduce risk of spills or accidental releases of hazardous materials.
HM-10: Utilize Spill Prevention Measures	Would reduce risk of potential spills.
WQ-1: Conduct Work from Top of Bank	Would reduce the effect of machinery on streambed and water quality.
WQ-2: Evaluate Use of Wheel and Track Mounted Vehicles in Stream Bottoms	Would reduce the potential effects of machinery and vehicles on stream bottoms.
WQ-4: Limits Impacts from Staging and Stockpiling Materials	Would reduce runoff and erosion and reduce impacts on instream biota and water quality.
WQ-5: Stabilize Construction Entrances and Exits	Would reduce runoff and erosion and reduce impacts on instream biota and water quality.
WQ-8: Minimize Hardscape in Bank Protection Design	Would reduce downstream or adjacent bank scour and erosion.
WQ-9: Use Seeding for Erosion Control, Weed Suppression, and Site Improvement	Would reduce the potential for erosion.
WQ-10: Prevent Scour Downstream of Sediment Removal	Would decrease scour downstream of sediment removal by grading the channel transitions and ensuring that there are no rapid changes in the slope.
WQ-11: Maintain Clean Conditions at Work Sites	Would require that work areas and access roads are maintained in an orderly condition and that materials or equipment left on site overnight are stored as inconspicuously as possible.

Sources: Valley Water 2014, 2019

Notes:

[1] SMP BMPs are only applicable to Project activities conducted at or near surface waters in areas downstream of Anderson Dam.

Key: AQ = Air Quality; BAAQMD = Bay Area Air Quality Management District; BI = Biology; BMP = best management practices; CU = Cultural Resources; EIR = Environmental Impact Report; GEN = General; HM = Hazards and Hazardous Materials; NOA = Naturally occurring asbestos; SMP = Stream Maintenance Program; TR = Transportation; WQ = Water Quality; VHP = Santa Clara Valley Habitat Plan

2.11.2 Valley Habitat Plan Conditions

The VHP is a joint Habitat Conservation Plan (HCP) and Natural Communities Conservation Plan (NCCP) developed to serve as the basis for issuance of incidental take permits and authorizations pursuant to Section 10 of the federal ESA, the California Endangered Species Act (CESA), and NCCPA (SCVHA, 2012). The Project is a covered activity identified in the VHP. Valley Water would adhere to applicable VHP conditions 1, 3, 4, 5, 7, 8, 11, 12, 13, 17, 19, and 20 ~~and 5~~, and all applicable VHP AMMs, including the aquatic habitat AMMs from the VHP (VHP Table 6-2) throughout Project implementation (**Table 2-21**). Valley Water would also pay applicable VHP impact fees, which are included in the Project as a Conservation Measure. The applicable VHP conditions and AMMs are included in Appendix A, *Best Management Practices and Santa Clara Valley Habitat Conservation Plan Conditions, Avoidance and Minimization Measures, and Mitigation Measures ~~Incorporated in the Project~~.* All VHP conditions and AMMs would be incorporated into the construction documents (plans and specifications).

2.12 Permits, Approvals, and Consultations

This EIR would be used by the regulatory agencies issuing permits, as well as for other agency approvals and consultations for the Project. **Table 2-22** ~~**Table 2-23**~~ provides a list of the agencies that are expected to use the EIR in their decision-making or consultations, and the applicable permits, approvals, and consultations that are expected to be required for the Project.

Table 2-22 ~~2-23~~. Regulatory Permits, Approvals, and Consultations for the Project

Agency	Permit / Approval / Consultation
Federal Agencies	
FERC – NEPA Lead Agency	FERC NEPA Regulations (18 CFR Part 2.80, 380) – oversight of conditional surrender of FERC hydroelectric license exemption and completion of NEPA process; lead federal agency for ESA Section 7 and NHPA Section 106 consultation
NMFS	ESA – Section 7 consultation on combined FOCP and the Project
	Magnuson-Stevens Act – Essential Fish Habitat Assessment on combined FOCP and the Project
U.S. Army Corps of Engineers	Section 404 of the Clean Water Act – permit or FOCP permit amendment
USFWS	ESA –authorization under incidental take provisions of the VHP for Covered Species and Activities –Section 7 consultation on the Project for non-Covered Species or Activities
State Agencies	
CDFW	Section 1600 et seq. of the California Fish and Game Code – Lake or Streambed Alteration Agreement
	California Endangered Species Act – authorization under incidental take provisions of the VHP for Covered Species and activities --Individual Section 2081 Permit for Non-Covered Species or Activities
DSOD	California Water Code, Division 3 – approval of repairs or alterations to a dam or reservoir California Code of Regulations, Title 23 – approval of dam safety and dam repairs or alterations
San Francisco Regional Water Quality Control Board	San Francisco Bay Region Municipal Regional Stormwater NPDES Permit (Order No. R2-2022-0018; NPDES Permit No CAS612008, as amended)
SWRCB	Section 401 of the Clean Water Act and Porter Cologne Water Quality Control Act – water quality certification Section 402 of the Clean Water Act – notification under Construction General Permit Order No. WQ 2022-0057-DWQ ~~2009- 0009-DWQ~~ Water rights license amendments California Statewide NPDES Permit for Discharges

Agency	Permit / Approval / Consultation
	from Drinking Water Systems (Order WQ 2014-0194-DWQ; NPDES No. CAG140001, as amended)
San Francisco Bay Conservation and Development Commission	Coastal Zone Management Act Consistency Certification
State Office of Historic Preservation	NHPA Section 106 consultation
Regional and Local Agencies	
BAAQMD	Authorities to Construct and Permits to Operate stationary source equipment
County of Santa Clara	County Floodplain Development Permit Approval of access/activities on County owned land and consultation on the reestablishment of recreational facilities Other County approvals applicable to Valley Water
City of San José	Cherry Flat Reservoir Cooperative Operating Agreement Other municipal approvals applicable to Valley Water
City of Morgan Hill	Encroachment permit, temporary right of entry
	Other municipal approvals applicable to Valley Water

Key: BAAQMD = Bay Area Air Quality Management District; CDFW = California Department of Fish and Wildlife; CFR = Code of Federal Regulations; DSOD = California Department of Water Resources, Division of Safety of Dams; ESA = federal Endangered Species Act; FERC = Federal Energy Regulatory Commission; FOCP = FERC Order Compliance Project; NEPA = National Environmental Policy Act; NHPA = National Historic Preservation Act; NMFS = National Oceanic and Atmospheric Administration – National Marine Fisheries Service; SWRCB = State Water Resources Control Board; USFWS = U.S. Fish and Wildlife Service; VHP = Santa Clara Valley Habitat Plan

2.12.1 Water Rights Amendments

In May 2015, Valley Water submitted proposed water rights amendments, or Petitions for Change, to the SWRCB to address technical aspects of the water rights subject to the FAHCE Settlement Agreement; these Petitions are being updated. The amendments are intended to update the water rights held in the Coyote Creek Watershed consistent with the FAHCE ~~FACHE~~ Settlement Agreement and implementation of FAHCE flow curve post-construction operation. Technical changes include correcting the locations of points of diversion and updating maps. The petitions also request that Valley Water's water rights licenses be amended to add Fish and Wildlife Preservation and Enhancement as a beneficial use of the diverted water. Chapter 5 of the FHRP supports the petitions as they propose modifying current operations to ensure that this beneficial use of water is achieved. Specific proposed water rights changes to Valley Water's Coyote Creek rights permits are listed in **Table 2-23** ~~**Table 2-24**~~**.**

Table 2-23~~2-24~~. Water Right Amendments Proposed

Permit Number	Facility/Water Source	Priority Date	Current Appropriation (Acre Feet per Year)	Diversion Period	Existing Purpose of Use	Change Proposed in Petition[1]
5061	Coyote Reservoir/ Coyote Creek	12/09/1931	24,560	10/01 to 07/01	Domestic, Irrigation, Minor Industrial and Incidental Recreation	Change Purpose of Use to Municipal, Minor Industrial and Fish and Wildlife Preservation and Enhancement
5062	Coyote Percolation Pond/Coyote Creek	07/10/1935	5,000	04/01 to 12/15	Domestic and Irrigation	Change Purpose of Use to Municipal, and Fish and Wildlife Preservation and Enhancement
8494	Anderson Reservoir/ Coyote Creek	04/04/1949	71,100	12/01 to 05/01	Domestic, Irrigation, Industrial, Recreational and Incidental Power	Change Purpose of Use to Municipal, Industrial, Incidental Power, and Fish and Wildlife Preservation and Enhancement
14704	Anderson Reservoir/ Coyote Creek	01/21/1963	20,180	10/01 to 07/01	Domestic, Industrial, Recreational and Incidental Power	Change Purpose of Use to Municipal, Industrial, Incidental Power, and Fish and Wildlife Preservation and Enhancement

Chapter 3
ENVIRONMENTAL AND REGULATORY SETTING AND IMPACT ANALYSIS

3.0 Introduction

Chapter 3 presents the environmental setting, regulatory framework, impacts, and mitigation measures applicable to the Project. Section 3.0, *Introduction* of Chapter 3, *Regulatory and Environmental Setting and Impact Analysis* introduces the common features used to assess impacts for each of the EIR's 22 resource topic areas, including the regional environmental setting, the definition of the Project baselines, and the definition of the analytical time horizon. This section also describes the overall organization of the environmental resource sections to follow and the approach to assessing impacts. Finally, based on an IS completed pursuant to *CEQA Guidelines* (Appendix B), this section identifies resource topic areas that were evaluated and found to have no potential for significant impacts based on the scope and nature of the Project activities and provides the justification for eliminating them from detailed analysis in this EIR.

3.0.1 Regional Environmental Setting and Project Area

As described in Section 2.2, *Project Location*, of Chapter 2, *Project Description,* the regional setting area (refer to Section 2.2.1 ~~2.1.1~~) for the purposes of this EIR is defined as the Coyote Creek Watershed, including mainstem tributaries and Valley Water water supply facilities where Valley Water holds corresponding water rights licenses.

The Project Area (refer to Section 2.2.2 ~~2.1.2~~), for the purposes of this EIR, is defined as the area and immediate vicinity within which all construction-related activities or ground disturbance would occur and the areas and facilities that would be operated through the implementation of the Project. The Project Area, including lands associated with both the Seismic Retrofit and Conservation Measure components, is described in detail in Section 2.2.2 ~~2.1.2~~ and shown in **Figure 2-3a** and **Figure 2-3b**. The Project Area includes Anderson Reservoir, Anderson Dam, Coyote Creek channel below Anderson Dam (including the tidally inundated portion of lower Coyote Creek and the waters of San Francisco Bay to the confluence with Alviso Slough for construction impacts), the Coyote Creek CWMZ, and lands in the immediate vicinity of Anderson Reservoir and Coyote Creek (owned by Valley Water, the County of Santa Clara, or by private landowners), as well as portions of the Cochrane Road and Coyote Road rights-of-way. Please note that specific study areas for each resource impact analysis are defined within the individual environmental resource topic sections; study areas can be larger than the Project Area in order to account for the full range of direct and indirect impacts that could result from the Project.

3.0.2 Environmental Baselines

Under CEQA, physical baseline conditions serve as the basis against which the incremental impacts of a proposed project are measured. The effects of Project implementation are compared with environmental baseline conditions under each resource topic. As described in *CEQA Guidelines* section 15125(a)(1):

> Generally, the lead agency should describe physical environmental conditions as they exist at the time the notice of preparation is published… [August 2013].
>
> Where existing conditions change or fluctuate over time, and where necessary to provide the most accurate picture practically possible of the project's impacts, a lead agency may define existing conditions by referencing historic conditions, or conditions expected when the project becomes operational, or both, that are supported with substantial evidence. In addition, a lead agency may also use baselines consisting of both existing conditions and projected future conditions that are supported by reliable projections based on substantial evidence in the record.

Each resource topic section (Sections 3.1 through 3.22) includes a description of the environmental setting for the resource topic in the relevant Project Area. Where appropriate, environmental baseline conditions are included in this description. For construction phase impacts, existing conditions at the time of the NOP (2013) are not used[1] because many environmental conditions have changed since 2013. Instead, either existing conditions based on data available at the time of EIR preparation or post-FOCP conditions (if FOCP implementation has changed these existing conditions) are generally used, which allows for a more accurate prediction of Project impacts. Where resources would be affected by proposed flow measures associated with post-construction operations, two modeled baselines are generally used. These are:

- "Pre-FERC Order Baseline" – represented by groundwater recharge operations to meet current consumer demand and Coyote Creek conditions immediately prior to the 2020 FERC IRRM Order (i.e., prior to the reservoir drawdown to deadpool and FOCP).
- "Future Baseline" – anticipated future, post-construction "business-as-usual" Anderson Dam operations without implementing FAHCE or flow regime improvements after all seismic safety improvements have been implemented, permitting the reservoir to return to maximum storage capacity, including groundwater recharge operations to meet future anticipated consumer demand and anticipated Coyote Creek conditions in the absence of drawdown, FOCP construction, and Project construction.

Construction and operational environmental baselines are further described below.

3.0.2.1 Existing Conditions Baseline

The baseline for evaluating the construction phase impacts of Seismic Retrofit components, downstream non-flow Conservation Measures, construction phase flow operations and flow Conservation Measures, and other physical elements of the Project generally relies on publicly accessible data and/or field observations representing existing conditions when this EIR was written. This baseline includes consideration of post-FOCP conditions where FOCP implementation has changed or will change existing conditions. In other words, "existing

[1] Under *CEQA Guidelines* Section 15025(a), existing conditions at the time of NOP publication are generally used as the environmental baseline, but due to the age of the Project EIR NOP, this EIR uses more recent information to provide a more accurate picture of Project construction impacts.

conditions" for Seismic Retrofit component construction, flow operations, and flow and non-flow measure implementation includes changes to the environment caused by construction of the FOCP upgrades to existing Anderson Dam and Reservoir facilities. Accordingly, for evaluation of construction phase impacts, environmental settings for resources near the Project Area and relevant study areas are described as they would exist following completion of the FOCP.

This existing conditions baseline applies to all resource topics and construction impacts. It is generally used to determine impacts of both physical facility Conservation Measure components construction, and impacts of construction phase reservoir operations and flow releases, including construction phase flow Conservation Measures. In addition, for water-related resource topics, the Pre-FERC Order Baseline is also generally used to analyze impacts of construction phase reservoir operations and flow releases, including construction phase flow Conservation Measures components.

With respect to construction phase flow operations and releases, the existing conditions baseline accounts for the reservoir drawdown condition and associated reduced flow operations mandated by the FERC Order, as well as the completion of the ADTP and downstream flood management measures as required by the FERC Order and resulting FOCP. The use of the existing conditions baseline is particularly important to obtaining an evaluation of the effects of the Project on conditions existing at the time the Project would be commenced, and is used when analyzing the biological resources and water resources (i.e., hydrology, water quality, groundwater) Project construction impacts.

3.0.2.2 Post-Construction Operational Impact Baselines

Background on Historical and Current Anderson Reservoir Operations

As discussed in Chapter 1, *Introduction*, between 2008 and 2012, several dam safety deficiencies associated with seismic shaking, fault offset, flood capacity, and emergency drawdown capabilities were identified that have been the catalyst for several voluntary and regulatory-agency-imposed reservoir restrictions. These restricted capacity conditions imposed prior to the 2020 FERC IRMM order became the "typical" historical operating condition for Anderson Reservoir and, therefore, are reflected by DSOD restrictions assumed to constrain Anderson Reservoir in the Pre-FERC Order Baseline condition described below.

Historically, water released for groundwater recharge incidentally has provided in-stream environmental flows for the FCWMZ, and in some cases downstream of the FCWMZ, and provided connectivity between Coyote Creek and San Francisco Bay. Historically, these releases have been made year-round, but releases have been generally higher in the summer when the groundwater basins are dryer and groundwater pumping is higher, which requires more water for percolation to meet water supply demands, while maintaining sustainable groundwater levels to prevent subsidence. Historically, flows from the reservoir's "cold pool" have been released primarily in summer and fall months, at times mixed with imported water flows from the CDL, to augment in-stream flows and to provide cooler temperature flows than would otherwise be present in the FCWMZ to benefit steelhead. In addition, Valley Water has historically been required to maintain a flow of 2.5 cfs past the Edenvale streamflow gage (SF58), which marks the end of the groundwater recharge zone, to keep the creek wet all the way to the San Francisco Bay per the Lake and Streambed Alteration Agreement (LSAA) that Valley Water has with CDFW (Valley Water 2020a).

In 2020, the FERC IRRM Order mandated that Valley Water must implement IRRMs (FERC 2020a), including additional drawdown to further restrict the reservoir at deadpool (i.e., elev. ~~488~~ 490 feet, equivalent to 2,850 AF of reservoir storage). This reservoir capacity limitation contributes to current existing conditions, which reflect drawdown and implementation of the FOCP. Due to restrictions imposed by the 2020 FERC IRRM Order on reservoir storage capacity, and, in turn, reductions in reservoir water available for operation, the amount of reduction in operational releases has varied from year to year since the FERC IRRM Order, based on non-reservoir watershed inflows, availability and quality of imported water, pipeline outages, groundwater supplies, and water demand. The FERC IRRM Order, subsequent FERC Orders (FERC 2020b and FERC 2021), and the resulting FOCP are not considered in the Pre-FERC Order Baseline because the Pre-FERC Order Baseline is intended to reflect a historical period of typical Anderson Dam operations, prior to the emergency FERC IRRM Order and FOCP implementation.

The Pre-FERC Order Baseline is used as the baseline for comparison of post-construction Project operations, allowing a comparison of post-construction typical operations with pre-dam retrofit typical operations. The Pre-FERC Order Baseline constitutes the Water Evaluation and Planning (WEAP) modeled historical typical operations baseline, reflecting historical DSOD ~~seismic~~ restrictions issued prior to the FERC IRRM Order *but not* the environmental conditions after implementation of the FERC IRRM Order and FOCP (which are the conditions captured by the existing conditions baseline described in section 3.0.2.1 above).

The operations described by the Pre-FERC Order Baseline continued with both voluntary and DSOD safety restrictions in place for many years prior to the FERC IRRM Order, limiting available water storage in Anderson Reservoir to some extent, until the February 2020 FERC IRRM Order severely limited storage in Anderson reservoir to deadpool. Therefore, the Pre-FERC Order Baseline is an appropriate historical typical operations baseline for evaluating effects of post-construction Project operations. Since the 2020 FERC IRRM Order, water supply and groundwater recharge operations and flow releases have continued with both historical DSOD restrictions *and* FERC IRRM Order restrictions in place.

Pre-FERC Order Baseline for Post-Construction Operational Impacts

For the purposes of this ~~Draft~~ EIR, the Pre-FERC Order Baseline describes the typical operational conditions with historical DSOD reservoir capacity ~~seismic~~ restrictions but prior to the FERC IRRM Order ~~seismic~~ restrictions and FOCP facility upgrades. The Pre-FERC Order Baseline is represented by a modeled projection of 2015 flow conditions using a hydrological period of record extending from 1990 through 2010[2] and is based on water demands and usage estimates from Valley Water's 2015 Urban Water Management Plan (UWMP; Valley Water 2016 ~~2015~~), which was then the most recent UWMP available for incorporation into the WEAP model. In addition to the 1990-2010 period of record and 2015 estimates of water supplies and demands, the Pre-FERC Order Baseline incorporates DSOD ~~seismic~~ restrictions for Anderson and Coyote Creek dams, prior to the emergency FERC IRRM Order restrictions (i.e., drawdown and FOCP implementation), as described in Chapter 1, *Introduction*. The historical DSOD reservoir capacity ~~seismic~~ restrictions, hydrological period of record, and 2015 UWMP water demands and usage

[2] The Pre-FERC Order Baseline is also consistent with the "current conditions" baseline in the FAHCE EIR, where the FERC Order was not assumed for Anderson operations, which assures evaluation of post-Project operations with ongoing operations in a manner consistent with recommendation of the FAHCE Advisory Committee regarding flow modeling and, specifically, the WEAP model.

reasonably represent typical normal operational conditions prior to the FERC IRRM Order restrictions.[3] Resource topics using this modeled Pre-FERC Order Baseline to evaluate post-construction impacts particularly include biological resources (focused on fisheries, riparian habitats, wetlands), hydrology, groundwater, water quality, and water supply.

For post-construction impact analyses of effects associated with the completion of seismic retrofit components, non-flow Conservation Measures, and other physical components of the Project, for all other resource topics, the Pre-FERC Order Baseline condition is generally not used. Instead, the baseline for assessment of post-construction impacts of completed physical facilities and improvements is existing conditions at the time of the Draft EIR preparation, including post-FOCP conditions when applicable (i.e., the Construction Phase Baseline). This baseline is used for the evaluation of post-construction impacts of completed facilities and improvements for resource topics, including aesthetics, agricultural and forestry resources, air quality, other terrestrial biological resources, cultural resources, energy, geology and soils, greenhouse gas (GHG) emissions, hazards and hazardous materials, land use and planning, noise and vibration, public services, recreation, transportation, tribal cultural resources, utilities and service systems, and wildfire.

Future Baseline for Post-Construction Operational Impacts

For the purposes of this ~~Draft~~ EIR, a Future Baseline for Anderson Reservoir post-construction operations is also sometimes used that represents projected conditions if business-as-usual operations were resumed after completion of the Project, without implementing FAHCE or flow regime improvements, but after all seismic safety improvements have been implemented, permitting the reservoir to return to maximum storage capacity. The purpose of adding a Future Baseline analysis is to isolate the incremental impacts and benefits of implementing the FAHCE rule curves after Project construction. The Future Baseline was modeled using the same hydrological period of record as the Pre-FERC Order Baseline; however, the Future Baseline model uses projected 2035 water demands and conditions as defined in Valley Water's 2015 UWMP (Valley Water 2016 ~~2015~~) and Water Supply Master Plan 2040 (Valley Water ~~2016a~~, 2019a). Elimination of DSOD dam restrictions, together with the data from the same hydrological period of record, and 2035 water demands are considered reasonably representative of future business-as-usual conditions. Future Baseline conditions are considered to evaluate post-construction operations impacts, particularly for the resource topics materially affected by changes in flow conditions. For these resource topics, the impacts of Project implementation as of 2035 are also compared to Future Baseline conditions.

3.0.3 Environmental Resource Topic Sections

This chapter, Chapter 3, discusses the approach to determining the regulatory and environmental setting used to determine significant impacts per each environmental resource section. Sections 3.1 through 3.22 of the ~~Draft~~EIR discuss the following environmental resource topics and impact analyses for the Project. The following environmental resource topics are analyzed in this EIR:

[3] The 2020 UWMP, an update to the 2015 UWMP, was adopted by the Valley Water Board of Directors in June 2021. Nevertheless, the 2015 UWMP continues to reasonably represent typical operating conditions prior to the severe FOCP restrictions.

- 3.1 – Aesthetics
- 3.2 – Agriculture and Forestry Resources
- 3.3 – Air Quality
- 3.4 – Biological Resources – Fisheries Resources
- 3.5 – Biological Resources – Wildlife and Terrestrial Resources
- 3.6 – Cultural Resources
- 3.7 – Energy
- 3.8 – Geology and Soils
- 3.9 – Greenhouse Gas Emissions
- 3.10 – Hazards and Hazardous Materials
- 3.11 – Hydrology
- 3.12 – Groundwater Resources
- 3.13 – Water Supply
- 3.14 – Water Quality
- 3.15 – Land Use
- 3.16 – Noise and Vibration
- 3.17 – Public Services
- 3.18 – Recreation
- 3.19 – Transportation
- 3.20 – Tribal Cultural Resources
- 3.21 – Utilities and Service Systems
- 3.22 – Wildfire

Sections 3.1 through 3.22 contain the following information about each resource topic:

- **Environmental and Regulatory Setting:** a description of the environmental and regulatory setting and background information about the resource topic to help the reader understand the resources that could be affected by the Project
- **Methodology and Approach to the Impact Analysis:** a description of the methodology and approach to the impact analysis, including a description for how potential (for and the severity of) impacts have been analyzed, usually broken into the following Project components:
    - Seismic Retrofit Construction: impact analysis associated with constructing the Seismic Retrofit components of the Project, including construction phase reservoir operations and flow releases when relevant to the resource topic
    - Conservation Measures Construction: impact analysis for the construction of proposed physical, non-flow Conservation Measures
    - Post-Construction Anderson Dam Facilities Operations and Maintenance: impact analysis for operational rule curve changes tied to non-emergency flow releases to occur following Anderson Dam facility upgrades and improvements
    - Post-Construction Conservation Measures Operation and Maintenance: impact analysis for the operation and maintenance of certain physical Conservation Measures components (Phase 2 Coyote Percolation Dam CM, Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, Sediment Augmentation Program, and Maintenance Activities at the Live Oak Restoration Reach) following their construction
    - Post-Construction Project and FAHCE Adaptive Management: programmatic impact analysis of implementing the Project and FAHCE AMP following Project construction

- **Applicable Best Management Practices and VHP Conditions:** a discussion of applicable BMPs~~,~~ and VHP Conditions~~, and mitigation avoidance and minimization measures~~ that would allow Valley Water to avoid, minimize, or compensate for Project impacts
- **Thresholds of Significance:** a discussion of the criteria and thresholds used in determining the significance of the Project's environmental impacts
- **Impact Analysis:** a discussion of the impacts of the Project on the resource, including a **bolded** determination of significance for each impact criterion
- **Mitigation Measures:** a description of feasible mitigation measures to avoid or substantially lessen significant impacts

3.0.3.1 Environmental and Regulatory Settings

Sections 3.1 through 3.22 include detailed descriptions of the environmental and regulatory settings of the Project specific to individual resource topics. The environmental setting section for each resource topic describes existing conditions and environmental baselines for the Project Area and the resource-specific study area. The regulatory setting section for each resource topic describes the applicable federal, state, and local laws, regulations, and policies that guide the protection and use of that resource, providing context for the Project and a basis for determining the Project's consistency with applicable plans and regulations.

3.0.3.2 Impact Analyses

The impact analysis for each resource topic covers the construction, construction phase operations, and post-construction operations and maintenance aspects of the Project components. Impacts are organized based on defined thresholds of significance, as introduced in each section. For this reason, in most resources, each resource topic includes individual impact headings. For example, if a resource topic area includes three thresholds of significance, there are three corresponding first-level impact headings (for example, Impacts AQ-1, AQ-2, and AQ-3). Each of these impact categories might then be further divided into a series of sub-impacts (for example, Impacts AQ-1a, AQ-1b, and AQ-1c) for which the same stated threshold is applied to multiple specific impacts.

Where applicable, avoidance and minimization measures (as listed in Section 2.10), including BMPs and VHP conditions (see Appendix A) relevant to each resource topic are identified at the beginning of that section, and the subsequent impact analysis assumes inclusion of these BMPs and VHP conditions as part of the Project. BMPs and VHP condition are further discussed within the context of each significant impact evaluation when they effectively reduce an adverse impact that would occur in the absence of the BMP or VHP conditions. Pre-mitigation impact significance findings rely on BMP or VHP condition implementation.

For significant impacts, feasible mitigation measures are proposed. Similar to the impact nomenclature, mitigation measures are denoted by the resource topic and numbered according to listing (i.e., taking air quality for example, Mitigation Measure AQ-1). Note that a mitigation measure established under one resource topic might also reduce an impact for another resource. These occurrences are identified and cross-referenced.

A statement of post-mitigation significance is provided based on applying the stated mitigation measures.

3.0.4 General Methodology

3.0.4.1 Impact Terminology

CEQA requires a lead agency to determine the significance of all environmental impacts (*CEQA Guidelines* section 15064). A threshold of significance for a given environmental impact defines the level of effect above which the lead agency considers impacts to be significant and below which considers impacts to be less than significant. Thresholds of significance are identifiable quantitative, qualitative, or performance levels for a particular environmental effect, whichever is most applicable to each specific type of environmental impact (*CEQA Guidelines* section 15064.7[a]).

The following terminology is used in this EIR to describe the various levels and types of environmental impacts associated with the Project:

- *Significance threshold:* A significance threshold is a criterion used by Valley Water, as lead agency under CEQA, to determine whether an adverse physical environmental impact would be significant.
- *Less-than-significant impact:* An impact is less than significant if the analysis concludes that the implementation of the Project would not result in environmental impacts that exceed the applicable significance threshold.
- *Significant impact:* An impact is significant if it would result in a substantial adverse change in the physical conditions of the environment, as determined by whether it exceeds the applicable significance threshold.
- *Significant and unavoidable impact:* An impact is significant and unavoidable if it would result in a substantial adverse physical change in the environment that cannot be feasibly mitigated to a less-than-significant level; that is, to a magnitude below the significance threshold.
- *Mitigation measure:* A mitigation measure is a feasible action proposed to be taken that would avoid or substantially lessen the magnitude of a significant impact. *CEQA Guidelines* section 15370 defines mitigation as:
    - Avoiding the impact altogether by not taking a certain action or parts of an action
    - Minimizing impacts by limiting the degree or magnitude of the action and its implementation
    - Rectifying the impact by repairing, rehabilitating, or restoring the impacted environment
    - Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action
    - Compensating for the impact by replacing or providing substitute resources or environments, including through permanent protection of such resources in the form of conservation easements
- *Feasible:* For purposes of defining feasible mitigation measures, *feasible* means capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors (*CEQA Guidelines* Section 15364).

3.0.4.2 General Approach to Analysis of Post-Construction Phase Flow Operational Rule Curves and Other Flow Conservation Measures

Hydrologic, hydraulic, water temperature, and fisheries habitat modeling and comparison to the Pre-FOCP Order Baseline and Future Baseline provide a quantitative basis from which to assess the effects of proposed post-construction operational rule curves and other flow Conservation Measures, as well as proposed operational rule curves under the Project (and the FAHCE Plus Alternative). Models and other tools applied in the evaluation of the Project post-construction flow operations (and the FAHCE Plus Alternative), which are described further in Sections 3.4, 3.5, 3.11, 3.12, 3.14 of the ~~Draft~~ EIR, include:

- Hydrologic modeling (WEAP model) to simulate mean daily river flows at specific nodes or points of interest (POI) downstream of Anderson Reservoir and average daily reservoir storage volumes
- Water temperature modeling to simulate mean daily river water temperatures at specific POIs downstream of Anderson Reservoir
- Hydraulic modeling at specific POIs and within defined stream reaches and habitat types downstream of Anderson Reservoir to simulate water depth, water velocity, and wetted area
- Fisheries habitat availability estimation modeling for steelhead and fall run Chinook salmon life stages to estimate the suitability and extent of physical habitat availability in defined reaches of Coyote Creek based on modeled flows, hydraulics, water temperatures, and habitat monitoring data
- Fish passage modeling for steelhead and fall run Chinook salmon to estimate the number of days when adults and juveniles would be able to pass designated POIs in Coyote Creek based on simulated water depths and water temperatures.

Note that the ~~Draft~~ EIR analysis relies on integrated flow measure modeling originally developed for the FAHCE program, which included the Stevens Creek, Guadalupe River, and Coyote Creek watersheds. This EIR analysis, however, considers the model results only as they apply to Coyote Creek Watershed.

Computer simulation models and postprocessing tools were used to assess changes in hydrology, hydraulics, water temperature, and associated changes in habitat conditions that could occur during construction, and under the Project (and alternatives) relative to baseline comparisons. Model predictions and results were used for comparative purposes, and the analysis focused on differences in the results among comparative scenarios.

The models used in the analyses, although mathematically precise, should be viewed as having some inherent uncertainty because of limitations in the theoretical basis of the models, underlying data availability, and the scope of the formulation and function for which each model is designed. Nonetheless, models developed for planning and impact assessment purposes produce credible and reliable representative results and constitute professionally acceptable analytic tools with which to conduct environmental evaluations of the Project (and alternatives).

3.0.4.3 General Approach to Analysis of Conservation Measures

The impact analysis for physical, non-flow Conservation Measures relies both on site-specific information, where the locations for construction and operation for Conservation Measures are generally known (e.g., Phase 2 Coyote Percolation Dam CM, Ogier Ponds CM, Sediment Augmentation Program, Maintenance of the North Channel Reach ~~Extension~~, and Maintenance Activities at the Live Oak Restoration Reach), and also on geographic information system (GIS) analysis of the stream reaches in the Project Area, where site-specific information is unknown but environmental resources within, and adjacent-to, those reaches would be impacted. The analysis of impacts from non-flow Conservation Measures components considers construction, operation, and maintenance impacts associated with these measures.

Where appropriate, the EIR proposes mitigation measures for significant impacts that would result from implementation of physical, non-flow Conservation Measures, with Valley Water assigned responsibility for implementation (e.g., Valley Water would directly implement mitigation measures for fish barrier remediation projects in Coyote Creek, since these projects would be directly implemented by Valley Water). In some cases, a Conservation Measure would be implemented by another entity, for example, when another entity owns the property on which the Conservation Measure would be constructed and would implement physical facilities or improvements on the property. In that case, Valley Water would require implementation of the mitigation measure(s) through agreement with the implementing entity. For example, Valley Water would add the mitigation measures as conditions of a funding agreement with the implementing entity.

3.0.4.4 General Approach to Analysis of Project Construction Monitoring and Post-Construction Attainment of Conservation Measure Success Criteria

As described in Chapter 2, *Project Description*, construction monitoring activities include data collection to monitor habitat environmental conditions (e.g., water quality, fisheries, sediment deposition, groundwater, invasive species), identify any changes that have or may result from construction activity to ecological functions and habitat values, and where feasible, adjust construction activities to prevent or reduce the effect of those changes on baseline environmental conditions, often in compliance with Project regulatory permits. For the purpose of the EIR analysis, impacts of the monitoring program are based on the physical impacts that might occur if these activities are implemented (e.g., the impacts of electrofishing on special-status fish species).

Monitoring also includes assessing post-construction performance objectives and success criteria to be attained by physical, non-flow Conservation Measures, namely through habitat restoration. While data collection and assessment might indicate that certain Conservation Measures are not satisfying success criteria specified for those measures, such as habitat vegetation cover, presence of particular-sized gravel and woody debris, or similar criteria, the actions that would be undertaken to attain prescribed success criteria would be largely identical to the methods described for implementation of the Conservation Measure.

3.0.4.5 General Approach to Project and FAHCE Adaptive Management Program

The FAHCE AMP would guide post-construction adaptive management of Project flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers and includes compliance, validation, effectiveness and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are evaluated for resource topics where impacts are expected.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measures construction. Impacts of adaptive actions are evaluated for resource topics where impacts are expected; impacts are evaluated at a programmatic level because the detailed characteristics, timing, and/or locations of the proposed adaptive measures are not known at the time of EIR preparation. Project-specific CEQA review would be undertaken in the future, as necessary, when specific projects would be proposed and project-specific details would be available.

3.0.4.6 General Approach to Analysis of Water Rights Amendments

Valley Water is proposing changes to its currently held water rights in Coyote Creek watershed as part of the Project. As discussed in Section 2.10.1, *Water Rights Amendments*, technical changes to water rights include correcting the locations of points of diversion and updating maps. The petitions also request that Valley Water's water rights licenses be amended to add Fish and Wildlife Preservation and Enhancement as a beneficial use of the diverted water. The water rights amendments require SWRCB (responsible agency) approval. However, the water rights amendments themselves would not cause any physical impacts in addition to the Project impacts. Therefore, impacts of the proposed Coyote Creek Watershed water right amendments are not evaluated separately in this EIR.

3.0.5 Resource Topics Dismissed from Further Review

The IS for the Project evaluated potential impacts in an Environmental Checklist (provided in Appendix B, *Notice of Preparation/Initial Study and Scoping Report*) and determined that some resource topics would have no significant impacts. These topics were eliminated from further analysis in the ~~Draft~~ EIR.[4] The discussion that follows explains the rationale behind dismissal of these resource topics and summarizes the determinations made in the IS.

3.0.5.1 Mineral Resources

The IS dismissed the topic of mineral resources from further analysis because no mineral, oil, or gas resource-producing areas or recovery sites are known to be located in the Project Area. In addition, the Project would not involve any activities that could directly affect mineral production sites or prevent future availability of mineral resources. Specifically, the Project would not:

- result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state
- result in the loss of availability of a locally important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan

Two on-site borrow areas have been identified as sources for the materials necessary to construct the Anderson Dam embankment and buttresses (see **Figure 2-4** in Chapter 2, *Project Description*). These areas have been identified as feasible for use as borrow areas for the Project, having the appropriate material types needed for construction. Based on the Economic Exclusion category presented in the *California Geological Survey Guidelines for Classification and Designation of Mineral Lands* (California Department of Conservation [CDOC] 2000), the materials from these borrow areas are not considered minerals of statewide importance, and the Project's use of the borrow areas also are not located in a locally important mineral resource recovery site (Santa Clara County 1994); therefore, the Project's use of the borrow areas would not affect future mining of mineral resources. Excavated materials would be used directly for dam reconstruction and would not be sold or distributed to other parties.

Some material required for Project construction may be obtained from offsite sources, but the quantity needed for construction of the Project would be relatively small and within the capacity of existing quarries.

In conclusion, Project construction activities would primarily rely on mineral resources found on site. Neither locally nor regionally important mineral resources are present within the Project Area that would become unavailable as a result of the Project, nor would the Project use a substantial quantity of mineral resources from off site or involve other activities that would adversely affect future mining in Santa Clara County. The Project would have no impact on mineral resources of local or statewide importance.

3.0.5.2 Population and Housing

The IS dismissed the topic of population and housing from further analysis because the Project would not involve the construction of new housing, induce growth, or disrupt or displace any existing housing units. Specifically, the Project would not:

[4] In some instances, the IS determined that certain impacts or entire topics would have no significant impacts; however, subsequent to filing the NOP, changes to the Project and/or new substantial evidence was made available to Valley Water, such that Valley Water has elected to carry forward these impact topics for further analysis in the ~~Draft~~ EIR.

- induce substantial unplanned population growth in an area, either directly (e.g., by proposing new homes and businesses) or indirectly (e.g., through extension of roads or other infrastructure[5]), that was not anticipated in approved local or regional planning documents
- displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere
- displace substantial numbers of people, necessitating the construction of replacement housing elsewhere

3.0.6 Approach to Cumulative Impacts

Cumulative impacts, as defined in Section 15355 of the *CEQA Guidelines*, refer to two or more individual effects that, when considered together, are considerable or that compound or increase other environmental impacts. The cumulative impact from several projects is the change in the environment that results from the incremental impact of the proposed project when added to other closely related past, present, and reasonably foreseeable probable future projects. Pertinent guidance for cumulative impact analysis is provided in Section 15130 of the *CEQA Guidelines*:

- An EIR shall discuss cumulative impacts of a project when the project's incremental effect is "cumulatively considerable" (i.e., the incremental effects of the proposed project are significant when viewed in connection with the effects of past, current, and probable future projects) (*CEQA Guidelines* Sections 15130[a] and 15065[a][3]).
- An EIR should not discuss cumulative impacts that do not result in part from the project evaluated in the EIR.
- A project's contribution is not significant if the Project ~~project~~ is required to implement or fund its fair share of a mitigation measure or measures designed to alleviate the cumulative impact.
- The discussion of impact severity and likelihood of occurrence need not be as detailed as for effects attributable to the project alone.
- The focus of analysis should be on the cumulative impact to which the identified other projects contribute, rather than on attributes of the other projects that do not contribute to the cumulative impact.

3.0.6.1 Approach to Cumulative Impact Analysis: List Approach

Two approaches to a cumulative impact analysis are discussed in *CEQA Guidelines* Section 15130(b)(1). The analysis can be based on (a) a list of past, present, and probable future projects producing related or cumulative impacts, or (b) a summary of projections contained in a general plan or related planning document. The analysis presented in this EIR employs the list-based approach.

[5] Note that the Project replaces and upgrades existing infrastructure (i.e., the dam and associated appurtenances); however, the Project would not extend infrastructure, nor does it increase capacity of existing infrastructure.

The criterion for considering whether a project is reasonably foreseeable and probable in this EIR is whether the project has been defined in adequate detail – for instance, through the completion of publicly available preliminary evaluations, feasibility studies, and/or draft environmental and engineering documents – to identify project impacts. Projects that were only in development – without detailed descriptions, operations criteria, or general locations – at the time that this cumulative impact assessment was written were not considered further.

In addition, the following factors were used to determine an appropriate list of projects for consideration in this cumulative analysis:

- **Similar Environmental Impacts.** A relevant project contributes effects on resources also affected by the Project. The Project could have either less-than-significant impacts or significant impacts that could contribute to cumulative impacts. Relevant projects in this cumulative analysis are those that could contribute impacts to the same environmental resources.
- **Geographic Location.** A relevant project is located within a defined geographic location for the cumulative effect. The potential for the Project to contribute to a cumulative impact arises if projects are located within the same geographic area.

The following terminology is used in this EIR to describe the various levels and types of cumulative environmental impacts associated with the Proposed Project:

- **Cumulative impact**: Under CEQA, a cumulative impact refers to an impact created as a result of the project evaluated in the EIR, together with impacts of other reasonably foreseeable probable projects causing similar impacts. A significant cumulative impact is one in which the cumulative effect would exceed the applicable significance threshold.
- **Significance threshold**: Like that used to evaluate the impacts resulting from the Project and alternatives, this is the criterion used in the EIR to determine whether the magnitude of a cumulative environmental impact would be significant.
- **Significant cumulative impact**: A cumulative impact is considered significant if it would result in a substantial adverse change in the physical conditions of the environment, as determined by whether it exceeds the applicable significance threshold.
- **Cumulatively considerable:** Incremental project impacts are cumulatively considerable, and thus significant, when they are significant when viewed in connection with the effects of other projects [*CEQA Guidelines* Section 15064(h)(1)]. *CEQA Guidelines* Section 15130(a) states that, if the contribution of the project to a significant cumulative impact is less than considerable, the incremental impact is less than significant.

3.0.6.2 *Geographic Scope of Analysis*

The area of analysis for the cumulative impact evaluations varies depending on the resource topic being analyzed. **Table 3.0-1** defines the geographic scope that is used in the cumulative impact analysis for each resource area.

Table 3.0-1. Geographic Scope for Resources with Potential Cumulative Impacts

EIR Section	Resource	Geographic Area of Analysis
3.1	Aesthetics	Local and regional – Individual component sites and local viewshed
3.2	Agriculture and Forestry Resources	Local and regional – Individual component sites and regional vicinity (i.e., Coyote Valley and southern Santa Clara County)
3.3	Air Quality	Regional – Bay Area Air Basin* and local for potential health risk impacts
3.4	Biological Resources – Fisheries Resources	Local and regional – Coyote Creek and Upper Penitencia Creek Watersheds; San Francisco Bay
3.5	Biological Resources – Wildlife and Terrestrial Resources	Regional – Coyote Creek Watershed, central Santa Clara County, and San Francisco Bay
3.6	Cultural Resources	Local – Individual component sites or other ground disturbance areas and immediate vicinity
3.7	Energy	Regional – Santa Clara County
3.8	Geology and Soils	Local – Individual component sites or other ground disturbance areas and immediate vicinity; Coyote Watershed
3.9	Greenhouse Gas Emissions	Regional – Bay Area Air Basin* and statewide
3.10	Hazards and Hazardous Materials	Local – Individual component sites and immediate vicinity
3.11	Hydrology	Local – Local watershed system and individual construction/grading sites Regional – Santa Clara County and San Francisco Bay
3.12	Groundwater Resources	Local and regional – Santa Clara and Llagas Subbasins
3.13	Water Supply	Local and regional – Santa Clara County
3.14	Water Quality	Local and regional – Coyote Creek, and Upper Penitencia Creek, watersheds; San Francisco Bay
3.15	Land Use and Planning	Local – Individual component sites and immediate vicinity
3.16	Noise and Vibration	Local – Immediate vicinity of individual component sites (i.e., typically within 0.5 mile or less, depending on the nature of the project noise source)
3.17	Public Services	Local – Service areas of public service providers
3.18	Recreation	Local and regional within 5 miles – Recreation facilities/areas near individual component sites; other nearby regional recreation facilities/areas that may serve as alternate recreational locations (see Table 3.18-1 for a comprehensive list of facilities).
3.19	Transportation	Local and regional – Roadway network within Santa Clara County (including local roadways and major freeways/roadways)

EIR Section	Resource	Geographic Area of Analysis
3.20	Tribal Cultural Resources	Local – Individual component sites or other ground disturbance areas and immediate vicinity
3.21	Utilities and Service Systems	Local and regional – Service areas of public utilities
3.22	Wildfire	Local and regional – Individual component sites and immediate vicinity; central Santa Clara County

**Bay Area Air Basin as regulated by Bay Area Air Quality Management District.*

3.0.6.3 Timing and Duration of Cumulative Impacts

This analysis assumes that cumulative impacts for seismic retrofit construction activities and Conservation Measures construction activities would take place over approximately <u>8</u> ~~10~~ years <u>starting in 2027.</u> ~~(spring 2026 through winter 20302 for work on the dam and spring 2032 through 2034 for the Ogier Ponds CM).~~ These construction-related impacts would be temporary and would only occur during construction of the proposed facilities and Conservation Measures.

Cumulative short-term operational impacts would take place within 3-5 years following construction, and long-term operational impacts are those that would persist after construction of the Project has been completed, the reservoir has been filled, and the reservoir returns to normal operations. To contribute to longer-term, permanent, or operational cumulative effects, other activities must be probable future projects that also have long-term effects.

3.0.6.4 Determination of Baseline Conditions for Cumulative Impact Analysis

For the ~~Draft~~ EIR cumulative impact analysis, specifically to account for FOCP impacts, the environmental baseline is defined as existing conditions prior to FOCP implementation (i.e., a Pre-FERC Order baseline). This baseline is used both for construction impacts and for operational impacts. This is in contrast to the Project baseline approach used for the resource impact analysis in Sections 3.1 through 3.22, described in more detail in Section 3.0.2, *Environmental Baselines*. The Pre-FERC Order baseline for operational impact analysis, including background on Anderson Reservoir operations, is described in Section 3.0.2.2.

3.0.6.5 List of Relevant Projects

Table 3.0-2 lists the past, present, and reasonably foreseeable future projects ("projects" also include certain plans and programs) considered in the cumulative impact analysis. These projects were reasonably foreseeable and probable at the time of Draft EIR preparation.

Land-based projects are primarily projects throughout Santa Clara County that could affect resources similar to or the same as those affected by the Project. The list was developed by reviewing CEQAnet, an online database of CEQA documents (including proposed projects), Valley Water's Five-Year Capital Improvements Program list, and current project lists and databases for the City of Morgan Hill, City of San José, and Santa Clara County. While not every potential cumulative project is specifically listed, the list of cumulative projects is considered to be sufficiently thorough, such that it represents the types of impacts that would be generated by these other projects.

Table 3.0-2. Probable Future Projects, Programs, and Plans Considered for Cumulative Impact Analysis

Project Description (Name, Sponsor, Source)	Location	Timeframe	Key Affected Resources
Water Supply and Water Quality Improvement Projects			
Anderson Dam FERC Order Compliance Project (FOCP) – Valley Water The FOCP is a set of actions to comply with the FERC IRRM order including: Drawdown of Anderson Reservoir to deadpool Construction and operation of Anderson Dam Tunnel Bank and rim stability improvements Coyote Creek Chillers Existing intake structure modifications Channel and bank erosion control modifications Cross Valley Pipeline Extension Inflatable bladder dam at Coyote Percolation Pond Coyote Creek Flood Management Measures Coyote Creek Habitat Restoration Measures Avoidance and Minimization Measures See Section 1.3.3 for details In addition to the FOCP activities discussed in Section 1.3.3, Valley Water has purchased 9 houses along the rim of the reservoir that are subject to landslide risk. The purchase, abandonment, and eventual demolition of these houses are done as part of FOCP reservoir stability improvements, near the Hoot Owl Way landslide. CEQA analysis would need to be completed prior to demolition of the structures. (Valley Water 2020b)	Coyote Creek	Under construction; completion in 2026 ~~2024~~	Aesthetics Fisheries Resources Terrestrial Resources Hydrology Groundwater Resources Water Supply Water Quality Recreation
Coyote Creek Flood Protection Project – Valley Water Improvements along approximately nine (9) miles of Coyote Creek, between Montague Expressway and Tully Road, in San José. The primary objective is to provide protection from floods up to the level that occurred on February 21, 2017, equivalent to approximately a 5% flood (20-year event). Project implementation is expected from 2022 to 2026. (Valley Water 2022a)	Coyote Creek	Construction 2025 – 2027 ~~2031~~	Fisheries Resources Terrestrial Resources Hydrology Water Quality

Project Description (Name, Sponsor, Source)	Location	Timeframe	Key Affected Resources
Pacheco Reservoir Expansion Project – Valley Water, San Benito County Water District, and Pacheco Pass Water District The Valley Water Board has approved an MOU between Valley Water, Pacheco Pass Water District and San Benito County Water District and approved an option to buy land for a new dam and expanded reservoir on the North Fork of Pacheco Creek that could hold 141,000 AF of water. Constructed in 1939 and used for groundwater recharge, the existing reservoir is located about 13 miles southwest of San Luis Reservoir, off Highway 152. (Valley Water 2021c~~b~~)	Pacheco Creek – Santa Clara County	Draft EIR released in 2021 Construction timing to be determined ~~2027 - 2034~~	Air Quality Terrestrial Resources Cultural Resources Energy GHG Emissions Water Supply Tribal Cultural Resources Utilities
Singleton Road Fish Barrier, Stream Restoration, and Pedestrian Bridge Project – San Jose Removal of the existing Singleton Road low-water crossing, restoration of a portion of Coyote Creek, and construction of a bicycle and pedestrian bridge. The removal of the existing low-water crossing barrier and restoration of Coyote Creek is to provide opportunities for protected and endangered aquatic species to migrate upstream to better spawning areas. (Valley Water 2023a~~b~~)	Coyote Creek	Completed 2021	Fisheries Resources Terrestrial Resources Hydrology Water Quality
Guadalupe Dam Seismic Retrofit Project – Valley Water Improvements to Guadalupe Dam to stabilize the embankment to withstand a Maximum Credible Earthquake; implement improvements as necessary for the Dam to safely pass the Probable Maximum Flood; ensure that the outlet works and hydraulic control system meet DSOD requirements; relocate the intake structure out of the upstream berm; and incorporate other measures to address seismic and other dam safety deficiencies that are identified through the Project delivery process. (Valley Water 2015b ~~2021b~~)	Guadalupe Watershed	Construction 2028 – 2031 ~~2030~~	Fisheries Resources Terrestrial Resources Groundwater Resources Water Supply
Almaden Dam Improvements Project – Valley Water Modification or construction of a new intake structure to meet DSOD regulatory standards; reconfiguration of the spillway as a result of potential findings from the reservoir's future probably maximum flood investigation; and correction of ongoing operation and maintenance issues to aging hydraulic lines, valves and energy dissipaters. The project also includes a separate future element to fix the Almaden-Calero Canal to restore operational capacity to the canal and stabilize and improve maintenance access; however, these improvements are on hold until Valley Water	Guadalupe Watershed	Construction 2030-2032 ~~2025 - 2031~~	Fisheries Resources Terrestrial Resources Groundwater Resources Water Supply

Project Description (Name, Sponsor, Source)	Location	Timeframe	Key Affected Resources
completes improvements at the Anderson, Calero, and Guadalupe Dams. (Valley Water 2015d ~~2018~~)			
Calero Dam Seismic Retrofit Project – Valley Water Improvements to the Calero Dam to stabilize the Calero Dam embankment to withstand a Maximum Credible Earthquake; modify or replace the outlet works if determined to be inadequate; modify the spillway or increase the freeboard of the dam for safe passage of the Probable Maximum Flood; provide modifications that do not preclude potential future expansion of dam and reservoir to provide additional reservoir storage; and remove or relocate the Bailey Ranch structures and breach Fellow's Dike. (Valley Water 2015a~~2021a~~)	Guadalupe Watershed	Construction 2027 ~~2032~~ - 2036	Fisheries Resources Terrestrial Resources Groundwater Resources Water Supply Recreation
Silicon Valley Purified Water Project – Valley Water Construction of facility to purify water treated at wastewater treatment plants for groundwater recharge or raw water augmentation. Includes construction of water conveyance pipelines, lateral pipelines, and associated facilities. Valley Water-wide Programs and Projects			
Fish and Aquatic Habitat Collaborative Effort – Valley Water FAHCE is a collaborative process to identify actions to balance fish and aquatic habitat needs with Valley Water's water supply operations. The program seeks to improve aquatic spawning and rearing habitat and fish passage for migration to and from the watersheds of the Coyote Creek, Stevens Creek, and Guadalupe River. The FAHCE ~~FAVCE~~ EIR evaluates impacts of implementing these measures in the Stevens Creek and Guadelupe watersheds. These measures include (a) modifications to reservoir operations to provide instream flows; (b) restoration measures to improve habitat conditions and provide fish passage; and (c) monitoring and adaptive management. Environmental and community benefits includes providing flows to improve habitat conditions; resolving water rights concerns; and complying with regulatory requirements. A Final Program EIR was issued in June 2023 that included project-level review for some project components. (Valley Water 2023b~~a~~)	Coyote Creek, Stevens Creek, and Guadalupe Watersheds	~~Final EIR released in June 2023~~ Project for Stevens Creek, and Guadalupe River approved in August 2023 and is currently being implemented. Numerous fish passage improvements have been completed.	Fisheries Resources Terrestrial Resources Hydrology Groundwater Resources Water Supply Water Quality Recreation

Project Description (Name, Sponsor, Source)	Location	Timeframe	Key Affected Resources
Stream Maintenance Program (SMP) – Valley Water The SMP removes sediment, manages vegetation, clears trash and debris, and stabilizes banks within channel reaches that have been modified for flood protection. Work is performed annually between June and October following approval of the season's proposed work by the regulatory agencies. The program also includes the removal of nonnative/invasive vegetation and management of upland vegetation on Valley Water properties to comply with local fire codes and ensure access to the channels for maintenance and emergency work. An SMP mitigation measure, Stream and Watershed Land Preservation, includes acquisition and preservation of land in the upper watersheds. (Valley Water 2019b)	Stevens Creek, Guadalupe Creek	Ongoing/long term	Fisheries Resources Terrestrial Resources Cultural Resources Geology and Soils Hydrology Groundwater Resources Water Supply Water Quality Noise Recreation Tribal Cultural Resources
Water Supply Master Plan 2040 (WSMP)– Valley Water The WSMP analyzes what additional water supplies and infrastructure are necessary for Valley Water to meet future water demand assuming population growth, climate change, regulatory changes in imported supplies, and infrastructure constraints. The WSMP identifies purified water, additional demand management and water conservation efforts, Pacheco Reservoir, Los Vaqueros Reservoir, and the Delta Conveyance Project as potential projects to pursue to ensure future water supply reliability. The Water Supply Master Plan is updated every five years. (Valley Water 2019a)	Santa Clara County	Ongoing, long term	Groundwater Resources Water Supply
2020 Urban Water Management Plan (UWMP) – Valley Water The 2020 UWMP complements other Valley Water water resource planning efforts including planning for annual operations, sustainable groundwater management, recycled water, integrated water resource management, and integrated regional water management. The UWMP documents current and projected water supplies and demands over the next 25 years during normal and drought years, as well as water reliability analysis and conservation efforts. The plan provides an overall picture of current and future water conditions and management in Santa Clara County. Most importantly, it provides the demand and supply projections that form the basis of Valley Water's Water Supply Master Plan and includes Valley Water's Water Shortage Contingency Plan (WSCP) establishing actions and procedures for managing water shortages due to droughts and other emergencies consistent with state regulations.	Santa Clara County	Ongoing	Groundwater Resources Water Supply

Project Description (Name, Sponsor, Source)	Location	Timeframe	Key Affected Resources
The Urban Water Management Plan is updated every five years. (Valley Water 2021c~~a~~)			
Countywide Water Reuse Master Plan (WRMP) – Valley Water The Countywide WRMP complements other plans, including the 2020 UWMP, to help meet Valley Water's Water Supply Master Plan 2040 goals. Valley Water initiated the WRMP to identify locally reliable, sustainable, and efficient recycled and purified water to address its water supply challenges. Valley Water's goal is to develop recycled and purified water to provide for at least 10% of the total County water demands by 2025. To achieve this, Valley Water plans to develop up to 24,000 acre-feet per year (AFY) of additional highly purified water for potable reuse by the year 2025 and support continued production and expansion of recycled water. Valley Water's planning evaluates development of up to 45,000 AFY of purified water for potable reuse. Valley Water finalized its Countywide WRMP in June 2021. (Valley Water 2021c)	Santa Clara County	Ongoing, long term	Groundwater Resources Water Supply
Encampment Clean Up Program – Valley Water Valley Water, working with the City of San José, removes illegal encampments on Valley Water-owned property to reduce damage to riparian habitat, reduce trash entering the waterway, and improve water quality. (Valley Water 2022b ~~2021o~~)	Coyote Creek, Guadalupe River	Ongoing, long term	Fisheries Resources Terrestrial Resources Hydrology Water Quality Utilities
Dam Maintenance Program – Valley Water The Dam Maintenance Program is comprised of four key elements – periodic engineering studies, surveillance and monitoring, inspection and maintenance, and emergency response and preparedness. Maintenance on the dams consists of vegetation management on the dam face, along access roads, and around infrastructure such as spillways, outlets, and control systems. (Valley Water 2012)	Valley Water dams in Santa Clara County	Ongoing, long term	Air Quality Fisheries Resources Terrestrial Resources Cultural Resources Energy Geology and Soils GHG Emissions Hydrology Groundwater Resources Water Supply Water Quality Noise Tribal Cultural Resources

Project Description (Name, Sponsor, Source)	Location	Timeframe	Key Affected Resources
Valley Water Additional Conservation and Stormwater Projects and Programs – Valley Water Incentivizing the use of advanced metering infrastructure; customer side leak repair incentives; graywater program expansion; rebates for the installation of rain barrels, cisterns, and rain gardens; partnerships to construct stormwater capture basins; and a flood- managed aquifer project. Implementation ongoing.	Santa Clara County	Operations: Potential changes to Valley Water supplies	Hydrology Groundwater Resources Water Supply Water Quality
Valley Water 10-Year Pipeline Inspection and Rehabilitation Program – Valley Water This program is intended to keep approximately 140 miles of large diameter water pipelines reliable. The work includes inspecting, repairing and replacing distressed pipe sections, defective or older valves and flowmeters. It also includes update of electric and control systems, repair corrosion protection systems and installation of a new pipeline monitoring system.	Valley Water pipelines in Santa Clara County	Ongoing, long term	Hydrology Groundwater Resources Water Supply Water Quality
Regional Projects			
San Francisco Bay Shoreline Protection Project – Valley Water, California State Coastal Conservancy, USACE, regional stakeholders This project is a partnership with the California State Coastal Conservancy, USACE, and regional stakeholders to provide tidal flood protection, restore and enhance tidal marsh and related habitats, and provide recreational and public access opportunities. Initial construction for flood protection is planned for of the San Francisco Bay shoreline between Alviso Slough and Coyote Creek in north San José and the community of Alviso. B.F. Sisk Dam Safety of Dams Modification Project and B.F. Sisk Dam Raise and Reservoir Expansion Project – Reclamation ~~San Luis & Delta-Mendota Water Authority and Reclamation Dam Safety Project~~: Raise sections of the B.F. Sisk Dam crest by 10 ~~12~~ feet and develop stability berms along sections of the embankment to address seismic issues. Dam Raise Project: Increase storage capacity in San Luis Reservoir by 130 TAF by raising the dam an additional 10 feet (beyond that proposed in the Dam Safety Project) to increase operational flexibility and improve water supply reliability for the CVP and SWP. (Reclamation 2019a Final EIS/EIR; Reclamation 2020 Final EIR/ Supplemental EIS)	San Luis Reservoir – Merced County	Final EIR for Dam Safety Project certified in 2020 Construction ~~2025~~ 2028 - 2032	Water Supply Water Quality

Project Description (Name, Sponsor, Source)	Location	Timeframe	Key Affected Resources
Reinitiation of Consultation on the Coordinated Long-Term Operation of the CVP and SWP – Reclamation Water flow operational changes and habitat restoration. Implementation ongoing. (Reclamation 2019b) – Final EIS	Statewide	Ongoing, long term	Water Supply
Non-Valley Water Projects			
Residential, Commercial, Industrial, and Recreation Area Development – Santa Clara County Santa Clara County, San José, Morgan Hill and other cities may implement a number of larger residential, industrial, commercial, and recreation area development projects that could impact similar resource areas are the Project. The build out of these projects would add impacts that are discussed in various EIRs, Specific Plans, and General Plan EIRs for relevant cities in Santa Clara County. Example projects include: Downtown West – Google (San Jose) Diridon Station Area Plan (San Jose) Moffett Park Specific Plan (Sunnyvale) Cochrane Commons Phase 2 (Morgan Hill) Five Wounds Urban Village / Downtown BART (San Jose) Mission Point Project (Santa Clara) Cochrane–Borello Residential Development Project (Morgan Hill) (Santa Clara County 2024 ~~2020~~, City of San José 2021~~b~~)	Santa Clara County	Current and ongoing	Air Quality Agriculture Terrestrial Resources Energy Geology and Soils GHG Emission Water Quality Noise Public Services Transportation Utilities
Santa Clara Valley Habitat Restoration Program – Santa Clara County, Santa Clara Valley Habitat Agency Santa Clara Valley Habitat Agency Reserve System involves land acquisition, restoration, and protection of an estimated 46,900 acres of land that accomplishes the following: Acquires and permanently protects an estimated 33,600 acres of land for the benefit of covered species, natural communities, biological diversity, and ecosystem function. Incorporates about 13,300 acres of existing open space areas and enhances the long-term management and monitoring on those lands within the Reserve System. Protects 100 miles of streams	Santa Clara County	Ongoing, long term	Fisheries Resources Terrestrial Resources

Project Description (Name, Sponsor, Source)	Location	Timeframe	Key Affected Resources
Restores up to 500 acres of riparian woodland and scrub, wetlands, and ponds and up to 10.4 miles of streams to offset losses and contribute to species recovery Provides management and monitoring of habitats on protected lands to enhance populations of covered species and maintain ecosystem processes. Preserves major local and regional connections between key habitat areas and between existing protected areas. (Santa Clara Valley Habitat Agency 2012 ~~2018~~)			
Santa Clara County Parks Planning Projects and Natural Resource Management – Santa Clara County Parks Santa Clara County Parks has a number of current planning and development projects in the Santa Clara County park system. Current projects include the following: Alviso Dock Feasibility Study Coyote Highlands – Coyote Canyon Interim Management Plan Sanborn County Park Master Plan Creekside and Meadowbrook Shelters Improvements Project Motorcycle County Park Site Improvements Project Los Gatos Creek Trail and Irrigation System Improvements Projects In addition, Santa Clara County Parks Natural Resource Management Program protects, enhances, and restores regional parks. Preservation of natural systems, biodiversity and special status species, and restoration of degraded habitats are all goals of the Santa Clara County Parks' Natural Resource Program. Programs within the Natural Resource Management Program include vegetation management, rare plants, inventory and monitoring, fisheries and wildlife and the trails program. (Santa Clara County Parks 2019)	Recreational areas of Santa Clara County	Ongoing	Fisheries Resources Terrestrial Resources Cultural Resources Water Quality Recreation Tribal Cultural Resources

3.1 Aesthetics

This section evaluates Project impacts on aesthetic and visual resources in the study area, defined below. The *CEQA Guidelines* significance criteria for aesthetics and visual resources address impacts related to the substantial damage to scenic resources within a State Scenic Highway, the substantial degradation to the existing visual character or quality of non-urbanized areas, or the creation of a new source of substantial light or glare that would adversely affect day or nighttime views to or from an area that may occur as a result of a Project.

The study area used to assess the Project aesthetic and visual resources impacts is the study area, which includes both the Seismic Retrofit components and Conservation Measure components that would be visible by the public or from public vantage points. These include public viewing opportunities from Anderson Lake County Park, Coyote Creek Parkway (largely from the Coyote Creek Trail), and public roads, including those within residential developments adjacent to Anderson Reservoir (Borello Ranch Estates and Holiday Lake Estates), Coyote Percolation Dam (California Maison), and US 101.

Note that the Anderson Dam and Reservoir, and the remainder of the Project Area, do not include remarkable landscape elements that create scenic vistas and have not been designated as scenic vista points in the Santa Clara County (County) General Plan, City of Morgan Hill General Plan, or the Envision San José 2040 General Plan. Therefore, impacts related to scenic vistas are not addressed in this section.

3.1.1 Terminology Overview

Aesthetics refers to visual resources and the quality of what can be seen or perceived in the environment, including characteristics such as building scale and mass, design character, and landscaping. Key terms used in this section to describe aesthetics are defined below.

Visual quality is the intrinsic appeal of a landscape or scene due to the combination of natural and built features. Visual quality consists of three visual features: visual character, viewer exposure, viewer concern, and visual sensitivity. These three visual quality features are defined below:

Visual character is the unique set of landscape features that combine to make a view, including native landforms, water, and vegetation patterns, as well as built features such as buildings, roads, and other structures. In urban settings, the visual character is primarily influenced by the land use type and density, urban landscaping and design, topography, and background setting.

Viewer exposure describes the degree to which viewers are exposed to views of the landscape. Viewer exposure considers landscape visibility, distance from which the landscape can be seen by viewers, number of viewers, and the duration of views.

Viewer concern addresses the general public's level of interest or concern of viewers regarding an area's visual resources and is closely aligned with viewers' expectations for the area. Viewer concern reflects the importance placed on a given landscape based on the human perceptions of the intrinsic beauty of the existing landforms, rockforms, water features, vegetation patterns, and cultural features. Viewer concern is generally rated as high, moderate, or low; where high viewer concern is represented by views that are appreciated frequently, for longer durations, and/or by receptors located within a short distance. In contrast, low viewer concern is characterized by views that are not regarded for intrinsic beauty and/or are not seen by many sensitive receptors or are only seen for short durations and from long distances where views are obstructed. Viewer concern ratings take into consideration viewer activity, view duration, viewing distance, adjacent land use, and special management or planning designation.

Visual sensitivity is the level of interest or concern that viewers and responsible land management agencies have for a particular visual resource. Visual sensitivity includes visual quality, viewer concern, and viewer exposure. Visual sensitivity is a measure of how noticeable proposed changes might be in a particular setting. The visual sensitivity is determined based on the distance from a viewer, the contrast of the proposed changes, and the duration that a particular view would be available to viewers. For example, areas such as scenic vistas, parks, trails, and scenic roadways typically have a high visual quality and visual sensitivity because these locales are publicly protected, appear natural, view durations are typically long, and close-up views are more commonly available.

As described above, natural and built features combine with viewer exposure and viewer concern to form varying degrees of visual quality, which are rated in this analysis as high, moderate, or low. The visual quality ratings are defined below:

- **High:** A high visual quality rating is defined as visual resources that are unique or exemplary of the region's natural or cultural scenic amenities, with high viewer exposure and/or concern.
- **Moderate:** A moderate visual quality rating is defined as visual resources typical or characteristic of the region's natural and/or cultural visual amenities, with moderate to high viewer exposure and/or concern.
- **Low:** A low visual quality rating refers to areas lacking in natural or cultural visual resource amenities typical of the region with low to moderate viewer exposure and/or concern, or visual resources typical or characteristic of the region's natural and/or cultural visual amenities with low visual exposure and/or concern.

3.1.2 Environmental Setting

The environmental setting describes the conditions of aesthetic and visual resources in the study area. This section describes the study area's existing visual character, viewer groups in the vicinity, scenic vistas, scenic highways, and light and glare. The environmental setting is based on two different baseline conditions that would form the basis for comparing Project impacts to visual resources. The baselines used in this section include the existing conditions baseline and Pre-FERC Order Conditions Baseline. The existing conditions baseline, which reflects reasonable assumptions of the study area's visual setting, would exist following the completion of the FOCP, based on available information at the time of EIR preparation (2023 ~~2022~~). The existing conditions baseline is used for evaluating the Seismic Retrofit and Conservation Measures construction impacts. For evaluating post-construction operation, the Pre-FERC Order Conditions Baseline is used. The Pre-FERC Order Conditions Baseline reflects general conditions at the time the NOP was filed in 2013. See discussion below for environmental setting and baselines conditions.

As described in Chapter 2 *Project Description,* the following recreational areas were closed as a result of the FOCP at the time of EIR preparation; these areas had previously provided public views of the study area:

- Toyon Group Picnic Area, Serpentine Trail, Dam Crest Trail, Cochrane Trail, and Woodchopper's Flat Picnic Area
- Anderson Dam Boat Ramp and Parking Area
- Coyote Road from the toe of the dam to the boat and vehicle parking areas
- Lakeview Trail (from the Anderson Boat Ramp Parking Area trailhead to the westernmost junction with the Rancho Laguna Seca Trail) in the Rosendin Park Area
- Fishing areas along the entire reservoir shoreline

Therefore, views from and within these areas during Seismic Retrofit Construction are not included in the impact analysis for visual resources.

3.1.2.1 Visual Character and Views

Regional Character

Anderson Dam and Reservoir are located in the County, 0.8 miles east of US 101, approximately 18 miles southeast from the downtown area of San José. The Project Area is located on land owned by Valley Water, the County, City of Morgan Hill, City of San José, and private property owners. The study area is within the jurisdictions of the County, City of Morgan Hill, and City of San José.

Morgan Hill is located in the southern part of Coyote Valley. The majority of Morgan Hill lies within a valley characterized by relatively flat topography that transitions to steep slopes along the western and eastern foothills. At the valley floor, Morgan Hill is at elev. 350 feet above mean sea level (Topographic-map.com 2021). Morgan Hill is largely comprised of residential land uses and commercial areas. Land uses surrounding Morgan Hill include rural residential development, agricultural lands, and open space that includes orchards and vineyards. Land uses to the east and west of Morgan Hill predominantly include undeveloped hillsides, and open space areas and reservoirs that include Anderson Reservoir, Anderson Lake County Park, and Coyote Lake to the east and Uvas Reservoir and Chesbro Reservoir to the west (City of Morgan Hill 2017 ~~2016~~).

San José is a largely urban environment adjacent to large open spaces, surrounded by natural settings that include the Baylands, redwood forests, Pacific Ocean, Santa Cruz mountains, and Monterey Bay area. Historically, development patterns in San José have focused on preserving the surrounding hillsides as open space, parklands, or natural habitat, providing the residents of San José with views of the natural environment and developing parklands and trails along San José's riparian corridors (City of San José 2023 ~~2012~~).

Project Area

Seismic Retrofit Components

Anderson Lake County Park is a 4,275-acre park that encompasses Anderson Reservoir and dam, Coyote Creek Parkway, Jackson Ranch Historic Park Site, Moses L. Rosendin Park (Rosendin Park

Area), and the Burnett Park Area (County 2021). Anderson Reservoir and recreation amenities along Coyote Creek, including multi-use trails and picnic areas located on Cochrane Road in Morgan Hill, east of US 101. The Jackson Ranch Historic Park Site can be accessed by following Dunne Avenue east from US 101, although it is closed to the public.

Anderson Dam is constructed of natural materials and is similar in color tones to the earthen shoreline. Serpentine grassland, chaparral, and oak woodland communities are present on the slopes above the reservoir. The dam embankment and immediate shoreline include a mix of native and non-native annual and perennial species typical of disturbed areas, such as wild oats, bromes, and mustards.

While Anderson Dam is visible from US 101, the Project Area for the Seismic Retrofit component is not located within the viewshed of any designated scenic highways (California Department of Transportation [Caltrans] 2021b). More distant views of Anderson Dam are accessible from local roads in the residential area to the west of the dam. However, due to distance, Anderson Dam and the Project Area for the Seismic Retrofit components are not located within the viewshed of any locally designated scenic routes, including East Dunne Avenue (County of Santa Clara 2008).

The Project Area for the Seismic Retrofit components includes lands in the immediate vicinity of Anderson Reservoir owned by Valley Water and the County, as well as portions of Cochrane Road and Coyote Road rights-of-way (**Figure 3.1-1** and **Figure 3.1-2**). These figures show the existing land uses within and adjacent to the Seismic Retrofit components, including recreational uses. These include Coyote Creek, parklands, and hiking trails (e.g., Coyote Creek Trail, Serpentine Trail), Rosendin Park (which includes Rancho Laguna Seco Trail, Lakeview ~~Lake View~~ Trail, and Gray Pine Trail), the Anderson Lake County Park Visitor's Center, an orchard, and private residences. Other facilities near the Seismic Retrofit components include the County Justice Training Center and the William F. James Boys Camp.

Pre-FERC Order Conditions Baseline

Figure 3.1-1 provides an overview of the locations under the Pre-FERC Order Conditions Baseline of land uses discussed above and includes viewpoints where representative photos have been taken from within the study area. Representative photos depicting the visual character of the Seismic Retrofit Components prior to FOCP under Pre-FERC Order Conditions Baseline are provided in **Figure 3.1-3** ~~**Figure 3.1-2**~~**.**

These photos were captured in October 2013, September 2014, and April 2018. In general, under the Pre-FERC Order Conditions Baseline, the visual quality of views from the dam crest looking toward the reservoir (Photo 7 in **Figure 3.1-3** ~~**Figure 3.1-2**~~) is considered high due to the expansive views of open water and undeveloped hillsides in the background. Under the Pre-FERC Order Conditions Baseline, the visual quality of views of Basalt Hill from the boat ramp parking area (Photos 11 and 12 in **Figure 3.1-3** ~~**Figure 3.1-2**~~) is moderate as the hillside includes trees and vegetation that are typical of the surrounding landscape. Similarly, the visual quality of more distant views of the Seismic Retrofit study area under Pre-FERC Order Conditions Baseline is also moderate, as the natural earth tones and vegetation on the dam and Basalt Hill are visually consistent with the surrounding natural landscape.

Since the time of the Pre-FERC Order Conditions Baseline, FERC required changes to be implemented in Anderson Dam and Reservoir, and since the beginning of construction of the FOCP, visual conditions have changed in the study area.

Existing Conditions Baseline

In 2020, the FOCP was implemented in response to a FERC order to address seismic vulnerability at Anderson Dam. The FOCP included changes that affected the visual character of the area, including drawdown of the reservoir. To capture these changes under the existing conditions baseline for impact analysis, **Figure 3.1-1** ~~**Figure 3.1-4**~~ shows viewpoint locations for the Project under the existing conditions baseline, including specific recreation areas at Anderson Lake County Park and the Conservation Measures area that provide public views of Seismic Retrofit components. **Figure 3.1-4** provides representative photos of these areas taken in June 2022, which include the Live Oak Picnic Area (Photos 10 and 11 in **Figure 3.1-4**) and trails within the Rosendin Park Area (see Photos 2, 3, and 4 in **Figure 3.1-4** which represent views from Gray Pine Trail). Photos 2 through 4 show the expansive views of the reservoir from the Gray Pine Trail and surrounding hills, Anderson Dam, the BHBA, and Morgan Hill to the west. As shown in Photo 10, scenic views of Coyote Creek, riparian trees, and the Serpentine Trail bridge crossing are accessible from the Live Oak Picnic Area of Anderson Lake County Park. Mature trees, passive recreation areas, and the BHBA are shown in Photo 11.

As shown in the photos in **Figure 3.1-4**, views of the Seismic Retrofit component are primarily visible from the residential area west of the dam, the Live Oak Picnic Area, the Rosendin Park Area, and the Holiday Lake Estates residential area to the south of the central portion of the reservoir. As shown in Photos 5, 7, 8, and 9, under the existing conditions baseline, views of construction equipment, materials, and staging areas associated with the FOCP can be seen. Low reservoir levels are also visible from Holiday Drive in the Holiday Lake Estates neighborhood and from the Gray Pine Trail in the Rosendin Park Area (Photos 1 and 2).

The overall visual quality from the residential areas and local roads under the existing conditions baseline is considered low-to-moderate due to the presence of large construction equipment, stockpiled materials, and construction activities associated with the FOCP. While those construction equipment, materials, and activities associated with the FOCP, such as for the ADTP, would be removed before construction of the Seismic Retrofit components; new construction equipment, materials, and activities would replace them. The visual quality from Rosendin Park Area is moderate due to the low reservoir levels, and the views from this area of the undeveloped hills are characteristic of the region. The visual character and visual quality from the Live Oak Picnic Area are moderate to high, as scenic views of riparian trees and Coyote Creek can be seen as shown in Photo 8.

Anderson Dam Seismic Retrofit Project
Environmental Impact Report

Source: Horizon Water and Environment 2022

Conservation Measure Components

Conservation Measures that involve construction of facility improvements or enhancements at Ogier Ponds (Ogier Ponds CM), the Coyote Percolation Pond (Phase 2 Coyote Percolation Dam Fish Passage Enhancements), and Maintenance of the North Channel Reach ~~Extension~~ may result in impacts to aesthetics. The locations of other Conservation Measures involving construction of facility improvements or enhancements (e.g., location(s) for in-stream restoration, placement of woody debris, and/or sediment augmentation) would generally occur within Coyote Creek between Anderson Dam and Ogier Ponds and around the Coyote Percolation Pond. The settings for these Conservation Measure areas are described below. The discussions and representative photographs of these locations reflect the existing conditions baseline.

Ogier Ponds

Both Ogier Ponds and the Coyote Percolation Pond are located within the Coyote Creek Parkway, which is operated and maintained by the County Parks and Recreation Department. Ogier Ponds is located approximately 4 miles downstream of Anderson Dam. Public views of Ogier Ponds are accessible from the Coyote Creek Trail and other public use trails parallel to the pond complex and from Ogier Avenue to the south. A photo of Pond 2 of Ogier Ponds is shown in Photo 14 of **Figure 3.1-4** ~~**Figure 3.1-2**~~. As shown in the photo, the Ogier Ponds complex is characterized by open water habitat with mature trees located along the perimeter of the ponds and surrounding grassland and chaparral vegetation communities. The visual character and visual quality of this area are characteristic of the surrounding landscape and thus considered moderate.

Coyote Percolation Pond

The Coyote Percolation Pond is located approximately 11 miles downstream of Anderson Dam. The pond is just north of Metcalf Park in San José and is accessible from the Coyote Creek Trail, which provides recreational opportunities, including birding, hiking, and fishing. Typical public views of the Coyote Percolation Pond area from the Coyote Creek Trail are shown in Photos 15 and 16 of **Figure 3.1-4.** The visual setting of the Coyote Percolation Pond is characterized by the pond and existing bladder dam, mature trees along the Coyote Creek Trail, the playground and grassy field at Metcalf Park (south of the percolation pond), and low-density residential development to the south. From the Coyote Creek Trail (shown in Photo 15), the bladder dam and Coyote Percolation Pond are not visible. Close-up views of the site are visible from an access road that connects to the Coyote Creek Trail. Motorists traveling on US 101 and Metcalf Road also have fleeting views of the internal access roads leading to the Coyote Percolation Dam. The visual character and visual quality of this area are characteristic of the surrounding landscape and therefore considered moderate.

Coyote Creek and Coyote Creek Parkway Trail

Public views of Coyote Creek are primarily accessible from the Coyote Creek Trail, which parallels the creek, as well as other multi-use trails in the Coyote Creek Parkway (e.g., Coyote

Canal Trail, Burnett Trail). Public views of the creek are also accessible from picnic areas such as the Live Oak Picnic Area, Walnut Rest Area, and Eucalyptus Rest Area. Visibility of Coyote Creek varies due to intervening trees, vegetation, and topography. Recreators, including hikers, equestrians, bicyclists, birders, and picnickers are provided partial views of the creek, mature trees, and riparian vegetation along Coyote Creek, and the surrounding hills. The visual character and visual quality of this area are characteristic of the surrounding landscape and considered moderate.

Maintenance of the North Channel Reach ~~Extension~~

~~The~~ Maintenance of the North Channel Reach ~~Extension~~ extends ~~is located~~ approximately 0.27 miles downstream of the existing outlet of Anderson Dam. ~~During~~ As part of the FOCP, weirs were constructed to restore flows within the historic North Channel of Coyote Creek to provide capacity to split dam outlet flows between the North and South Channels, and the channel was graded and restored with a wetland bench and wetland/riparian plantings. This Conservation Measure involves maintenance of ~~extends the limits of~~ the North Channel Reach constructed as part of the FOCP to reconnect the historic North Channel with the South Channel. These activities ~~reconstructed North Channel~~ would occur on ~~extend through~~ County Parks and portions of private property. Public views of the North Channel Reach ~~Extension area~~ are limited to the Live Oak Picnic Area. The visual character and visual quality of this area are characteristic of the surrounding landscape and considered moderate.

Live Oak Restoration Reach

As part of the FOCP's HMMP, Valley Water implemented spawning gravel and rearing habitat improvements in the Live Oak Restoration Reach directly downstream of Anderson Dam. This Conservation Measure includes the maintenance and monitoring of the gravel and woody debris restoration areas within the Live Oak Restoration Reach. This Conservation Measure includes the placement of up to ~~approximately~~ 10 cy of spawning gravel in the South Channel every five years ~~coarse sediment into the Live Oak Restoration Reach~~. Additionally, as part of the Sediment Augmentation Program described below, up to 500 cy of sediment would be added every five years within the Live Oak Restoration Reach or Ogier Ponds Restoration Reach. The maintenance activities would occur along the South Channel of Coyote Creek. This area is surrounded by parklands and is largely undeveloped within an established riparian corridor. Similar to the North Channel, public views of the South Channel area are limited to the Live Oak Picnic Area. The visual character and visual quality of this area are characteristic of the surrounding landscape and considered moderate.

Sediment Augmentation Program

The Sediment Augmentation Program would consist of placing up to 500 cy of sediment/gravel materials in the Coyote Creek Channel at various locations within the Live Oak Restoration Reach ~~between Anderson Dam~~ or ~~and~~ Ogier Ponds Restoration Reach, with initial placement within the Live Oak Restoration Reach. Sediment loads would be delivered by trucks, transported on conveyer belts, and placed in the creek using standard construction equipment. Sediment placement locations would be selected depending on existing access routes to the creek for construction equipment (dump trucks), creek flows at the time of placement, and the minimization of impacts to the riparian corridor. The visual quality of the sediment placement locations would be characteristic of the surrounding landscape and considered moderate; these areas would include open water stream/creek, grasslands, and public trails.

Post-Construction Operations, Maintenance, and Adaptive Management for Anderson Dam Facilities and Conservation Measures

The Project Area for the post-construction phase includes Anderson Dam and Anderson Reservoir, the Conservation Measure components described above and approximately 11 miles of Coyote Creek downstream of Anderson Dam. Once construction is completed, the following recreation areas at Anderson Lake County Park would provide public views of the Seismic Retrofit components: the Live Oak Picnic Area, Serpentine Trail, Anderson Boat Ramp Parking Area, Coyote Road, and trails within the Rosendin Park Area (i.e., Lakeview Trail, Gray Pine Trail, Rosendin Trail, and Rancho Laguna Seca Trail). These recreation areas include varying degrees of views of scenic resources. Conditions include expansive and close-up views of Anderson Reservoir that are accessible from the Anderson Boat Ramp Parking Area and Rosendin Park area; and views of mature trees are accessible from the Live Oak Picnic Area and Serpentine Trail.

3.1.2.2 Views of the Viewer Groups

Seismic Retrofit Components

Resident Views from Public Roadways

As a viewer group, residents have a heightened sensitivity to the surrounding viewshed, because they have a high frequency of views of an area and views of long durations (high viewer exposure). They also have a heightened appreciation for the aesthetic environment (e.g., landforms, rock formations, water features, and vegetation patterns) surrounding their residences (high viewer concern). Typically, viewer concern and visual sensitivity of residents increases with higher visibility of and more frequent exposure to the visual resources.

In general, residents along roadways near the reservoir shoreline, particularly in the Holiday Lake Estates neighborhood, have views of the reservoir, although the visual character of these views has been substantially degraded (as necessitated by the FOCP), because the reservoir is presently maintained at deadpool ~~elev. 488 feet~~. This lowered water surface elevation has resulted in large expanses of dry reservoir bed. Because of distance, public views of FOCP staging areas, work areas, and construction vehicles and equipment are limited.

Viewer exposure from public roadways in residential areas is considered moderate to high because the number of viewers and landscape visibility are low to moderate, but the duration of views from roadways is potentially high. Viewer concern of and visual sensitivity to the area, including the Seismic Retrofit component, is assumed to be moderate. Because the visual character of the reservoir as altered under the existing conditions baseline is low, visual quality is low to moderate.

Pre-FERC Order Conditions Baseline

The Project Area for the Seismic Retrofit component is visible from public roadways located to the west of the dam, largely within the Borello Ranch Estates. Additional ranch-style residences are located along Cochrane Road, also west of the Project Area. Representative views from public roadways within residential developments located west of Anderson Dam and Reservoir are shown in **Figure 3.1-3** ~~**Figure 3.1-2**~~**,** Photos 13 through 15. These photos show typical Pre-FERC Order Conditions Baseline views of Anderson Dam and the BHBA from Cochrane Road.

Existing Conditions Baseline

Figure 3.1-4 ~~**Figure 3.1-2**~~, Photo 12, shows a typical view from the Borello Ranch Estates development on Via Sebastian, just south of Cochrane Road, under the existing conditions baseline. Under the existing conditions baseline, public roadways within the Borello Ranch Estates neighborhood, located immediately west of the dam Seismic Retrofit component, have varying degrees of views of the FOCP work areas including, but not limited to, staging areas, work areas, and construction vehicles and equipment.

South of and uphill from Borello Ranch Estates is the Holiday Lake Estates neighborhood, which offers public views of the reservoir from public roadways. This neighborhood is located immediately south of the central and eastern portions of Anderson Reservoir (see **Figure 3.1-4** ~~**Figure 3.1-2**~~, Photo 1 for a typical view of the reservoir from Holiday Drive under the existing conditions baseline).

Residents along roadways near the reservoir shoreline, particularly in the Holiday Lake Estates neighborhood, have views of the reservoir, although the visual character of these views has been substantially degraded (as necessitated by the FOCP) because the reservoir is presently maintained at deadpool ~~elev. 488 feet~~. This lowered water surface elevation has resulted in large expanses of dry reservoir bed. Because of distance, public views of FOCP staging areas, work areas, and construction vehicles and equipment are limited.

Residential viewer exposure is considered moderate to high, because the number of viewers and landscape visibility are low to moderate, but the duration of views from roadways is potentially high. Residential viewer concern of and visual sensitivity to the area, including the Seismic Retrofit component, is assumed to be moderate. Because the visual character of the reservoir as altered under the existing conditions baseline is low, visual quality is low to moderate.

3.1.2.3 Scenic Vistas

A *scenic vista* is defined as a viewpoint that provides expansive views of a highly valued landscape for the benefit of the general public. Scenic vistas are also typically designated by an agency or department that actively manages the scenic vista to maintain or protect the public view through the provision of public access, information, safety, and protection of resources (e.g., signage, parking area, and safety fencing/rails). The study area does not provide expansive views of a highly valued landscape for the benefit of the general public and is not designated as a scenic vista in Caltrans' Scenic Route Program (Caltrans 2024 ~~2018~~), Envision San José 2040 General Plan (City of San José 2023 ~~2011~~), City of Morgan Hill General Plan (City of Morgan Hill 2017 ~~2016~~), or the *Santa Clara County General Plan* (County 1994).

3.1.2.4 Scenic Highways and Corridors

There are no state-designated scenic highways near the Project (Caltrans 2021b). As described in the *Regulatory Setting* section, the closest locally designated scenic corridors or scenic routes to the Project Area include US 101 (from Metcalf Road to Burnett Avenue) (City of San José 2023

~~2011~~) and East Dunne Avenue (County 2008). While Anderson Dam is visible from US 101 from a distance, the Project Area for the Seismic Retrofit components is not visible from this highway. While East Dunne Avenue provides views of the eastern portion of Anderson Reservoir, the dam and Seismic Retrofit components are not visible from this road due to distance and intervening topography and vegetation. Gateways identified in Policy CNF-19.2 of the *City of Morgan Hill General Plan* are outside the study area.

3.1.2.5 Light and Glare

Nighttime lighting is necessary to provide and maintain safe, secure, and attractive environments. Light that falls beyond the intended area of illumination is referred to as "light trespass." The most common cause of light trespass is spillover light, which occurs when a lighting source illuminates surfaces beyond the intended area, such as when building security lighting or parking lot lights shine onto neighboring properties. Spillover light can adversely affect light-sensitive uses, such as residences at nighttime. Both light intensity and fixtures can affect the amount of light spillover emitted from a source. Modern energy-efficient fixtures that face downward, such as shielded light fixtures, are typically less obtrusive than older upward-facing light fixtures. Glare is caused by light reflections from pavement, vehicles, and building materials such as reflective glass, polished surfaces, or metallic architectural features. During daylight hours, the amount of glare depends on the intensity and direction of sunlight.

Throughout the Project vicinity, the primary sources of nighttime lighting and glare are associated with the urban areas of Morgan Hill. Within the Project Area, nighttime lighting and glare are less pronounced and typically associated with residential uses and safety lighting in parking areas.

3.1.3 Regulatory Setting

3.1.3.1 State Laws, Regulations, and Policies

California Scenic Highway Program

In 1963, the California State Legislature established the California Scenic Highway Program, a provision of the Streets and Highways Code, to preserve and enhance the natural beauty of California (Caltrans 2021a). The state highway system includes designated scenic highways and those that are eligible for designation as scenic highways. According to the California Scenic Highway Mapping System, there are no officially designated scenic highways within or with views of the study area (Caltrans 2021b).

3.1.3.2 Regional and Local Laws, Regulations, and Policies

Santa Clara County General Plan

The Santa Clara County General Plan (County 1994) lists strategies and polices related to scenic resources in its Parks and Recreation and Resource Conservation chapters (County 1994). In 2008, the County updated the Regional Parks and Scenic Highway Map Element of the General Plan (County 2008). According to the Santa Clara County General Plan, there are existing parks and trails that are designated scenic resources within the Project Area. Anderson Lake County Park and the Coyote Creek Parkway are shown as both "existing" and "proposed" parks on the

Regional Parks and Scenic Highway Map. However, both these recreational amenities have been fully constructed at the time of the publishing of the Draft ~~is~~ EIR. East Dunne Avenue is also identified as a scenic rural route on the Regional Parks and Scenic Highway Map (County 2008).

City of Morgan Hill 2035 General Plan

The City of Morgan Hill 2035 General Plan (City of Morgan Hill 2017 ~~2016~~) includes a goal and policy relevant to aesthetic and visual resources impacts from the Project (City of Morgan Hill 2017 ~~2016~~). The City of Morgan Hill 2035 General Plan goal and policy relevant to aesthetic impacts are stated below.

Natural Resources and Environment

Goal NRE-5: Preservation and reclamation of streams and riparian areas as open space.

> **Policy NRE-6.4**: Tree Preservation and Protection. Preserve and protect mature, healthy trees whenever feasible, particularly native trees, historically significant trees, and other trees which are of significant size or of significant aesthetic value to the immediate vicinity or to the community as a whole.

Envision San José 2040 General Plan

The Envision San José 2040 General Plan (City of San José 2023 ~~2011~~) contains goals and policies regarding visual resources. These goals, supporting policies, and actions are primarily addressing access to scenic resources (Goal CD-9) and maintaining attractive gateways within the city boundaries (Goal CD-10), particularly along "Grand Boulevards" and "Rural Scenic Corridors." According to the Envision San José 2040 General Plan's Scenic Corridors Diagram, US 101 (from Metcalf Road to Burnett Avenue) is designated as a rural scenic corridor (City of San José 2023 ~~2011~~).

3.1.4 Methodology and Approach to Impact Analysis

This impact analysis describes the visual changes that would occur from implementing the Project using the standards of visual quality, visual character, viewer exposure, and visual sensitivity typically used for a visual assessment. The analysis focuses on reasonably foreseeable effects of the Project related to aesthetics based on a review of the following maps, photographs, and plans:

- County Parks Department's guide maps of Anderson Lake County Park and Coyote Creek Parkway
- Scenic corridor maps from the Envision San José 2040 General Plan, Santa Clara County General Plan, and City of Morgan Hill General Plan
- Aerial maps (i.e., Google Earth and GIS maps) showing the study area and vicinity
- Pre-FERC Order Conditions Baseline photos (shown in **Figure 3.1-3** ~~**Figure 3.1-2**~~)
- Existing Conditions Baseline photos (shown in **Figure 3.1-4**)

Site photographs represent the Pre-FERC Order Conditions and Existing Conditions baselines following FOCP implementation. Prior to taking site photos, key viewpoints were selected based on reviewing Google Earth and Google Maps to determine where publicly accessible views of the study area were available, including areas with higher visual sensitivity (e.g., recreational trails, parks, scenic roads, etc.) and viewer exposure.

The analysis considers temporary impacts that may occur during the 7-year construction period, as well as permanent impacts that would be long-term and/or that would result from ongoing facility operations and maintenance activities.

The direct effects of the Project are described and evaluated according to significance criteria from Appendix G of the *CEQA Guidelines*, discussed below. Lead agencies have discretion to determine that only impairment of public views, and not private views from a few residences, would be considered visual impacts that could be significant. This impact analysis considers only public views.

The assessment of impacts for the purposes of this section has been divided into construction-related impacts and operation-related impacts by Project component, as identified in and described in **Table 2-1** of Chapter 2, *Project Description*. Each component has been analyzed to determine whether the construction or operation of that component would substantially damage scenic resources, substantially degrade the existing visual character or quality in non-urbanized areas, or create a new source of substantial light or glare that would adversely affect day or nighttime views in the area.

3.1.4.1 Seismic Retrofit Construction

Project construction associated with the Seismic Retrofit components would result in temporary disruptions to, and in some cases temporary closure of, existing recreational facilities or opportunities that provide views of the Project Area in and around Anderson Reservoir. In addition, the Project would result in permanent changes to views of the Project Area. The analysis for construction-related impacts focuses on evaluating the Project's effects on existing public views from which project construction activities would be publicly visible. This analysis also evaluates the effects on public views from changes in Anderson Reservoir elevation levels throughout the construction period. The analysis relies primarily onsite photos and tools, such as Google Maps and GIS analysis of the study area to locate public viewing opportunities of the dam. This analysis does not consider views from existing recreational facilities that would be closed throughout the Seismic Retrofit construction phase. The potential for seismic retrofit construction activities to result in a significant visual impact is evaluated.

As described in Section 3.0, *Introduction,* the baseline for evaluating Seismic Retrofit construction effects is the existing conditions baseline at the time of the EIR preparation modified by FOCP implementation.

3.1.4.2 Conservation Measures Construction

As part of the Project, the Conservation Measure component includes the Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, Maintenance Activities at the Live Oak Restoration Reach, Sediment Augmentation Program, and Phase 2 Coyote Percolation Dam CM. Project construction associated with the Conservation Measures would result in temporary and permanent effects to aesthetic resources. A permanent effect on aesthetic resources would occur if the Conservation Measure involved aboveground elements that would substantially alter the visual character or quality of views in the area of a specific Conservation Measure. Similar to the methods described above, the analysis for construction-related impacts is based on the evaluation of the existing public views and changes to the existing views that would be publicly viewable due to Project construction. The analysis relies primarily on-site photos and tools, such as Google Maps and GIS analysis of the study area to locate public viewing opportunities along Coyote Creek downstream of Anderson Dam to Coyote Percolation Ponds, Ogier Ponds, and Coyote Percolation Ponds. As described in Section 3.0, *Introduction*, the baseline used for evaluating Conservation Measure construction effects is the existing conditions baseline at the time of the Draft EIR preparation modified by FOCP implementation.

3.1.4.3 Construction Monitoring

Construction monitoring activities are not considered in the impact analysis, as monitoring would involve data collection, and would not result in adverse changes to visual resources.

3.1.4.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

This analysis considers how post-construction reservoir operations would change the visual character and quality of views of Anderson Reservoir and Coyote Creek from non-emergency flow releases, following completion of the Seismic Retrofit construction. This analysis compares post-construction reservoir operations ~~(i.e., the future conditions baseline)~~ against both existing conditions baseline and the Pre-FERC Order Conditions Baseline.

Valley Water would maintain the newly retrofitted Anderson Dam and Reservoir per Valley Water's existing DMP. Maintenance of Anderson Dam facilities was previously evaluated in the Final DMP Program EIR prepared in January 2012 (Valley Water 2012). The DMP EIR includes mitigation measures to reduce impacts to visual resources, including the following:

- **Mitigation Measure AES-1**, which requires that fencing used be designed to blend in with the natural landscape and be non-reflective
- **Mitigation Measure AES-3**, which requires directing light downward and away from residences and reducing bulb wattage
- **Mitigation Measure GEO-1**, which requires removal and revegetation of temporary access roads when they are no longer needed

Aesthetic impacts associated with post-construction maintenance activities would not differ substantially from those impacts identified in the DMP EIR. Furthermore, the previously identified DMP impacts would not be exacerbated with implementation of the Seismic Retrofit components. Therefore, no new impacts would occur as a result of post-construction dam maintenance activities. For these reasons, post-construction dam maintenance activities are not discussed further in this section.

3.1.4.5 Post-Construction Conservation Measures Operations and Maintenance

The Conservation Measures focus on improving fish habitat (e.g., Maintenance Activities at the Live Oak Restoration Reach and Sedimentation Augmentation Program, separation of Coyote Creek from Ogier Ponds, ~~reopening~~ Maintenance of the North Channel Reach, and fish passage improvements at Coyote Percolation Dam). These Conservation Measures would operate passively, without mechanical or human intervention, and have been planned in accordance with Anderson Dam Reservoir flow releases. While data collection and assessment may indicate that individual Conservation Measures are not meeting success criteria specified for those measures, the modified Conservation Measure actions that would be undertaken to attain the prescribed success criteria would be similar to the original actions, and would not result in additional impacts. In the event that modified Conservation Measures would result in additional environmental impacts that are outside the scope of impacts analyzed in this EIR, the modified Conservation Measures would be subjected to additional CEQA at that time.

Maintenance of the Phase 2 Coyote Percolation Dam CM, Live Oak Restoration Reach, North Channel Reach ~~Extension~~, and groundwater recharge within Coyote Creek would be conducted in accordance with existing Valley Water maintenance programs (e.g., SMP for certain work activities within streams and DMP for Coyote Percolation Dam CM). BMPs and AMMs associated with these programs would be implemented to minimize potential aesthetics impacts during operations and maintenance activities. For activities included in the SMP, impacts from Conservation Measure operation and maintenance would be similar to those already disclosed in the SMP EIR. Therefore, operations and maintenance of Conservation Measures would not result in substantial adverse effects on scenic resources or the visual character or visual quality of the areas surrounding Conservation Measures. Therefore, this topic is not discussed further in this section.

3.1.4.6 Post-Construction Project and FAHCE Adaptive Management

The Project and FAHCE AMP would guide post-construction adaptive management of project flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are not evaluated in the impact analysis because the monitoring activities would not physically alter the landscape within the viewshed on a temporary or permanent basis.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. Impacts of these adaptive actions are considered in this impact analysis at a programmatic level as the detailed characteristics, timing, and/or locations of the proposed adaptive measures are not known at the time of this EIR's preparation. Project-specific CEQA review would be undertaken in the future, as necessary, when specific projects are proposed and project-specific details are available.

3.1.4.7 Applicable Best Management Practices and VHP Conditions

As noted in Section 2.0, *Project Description*, Valley Water would incorporate Valley Water BMPs, VHP Conditions, and AMMs to avoid and minimize adverse effects on the environment that may result from the Project. All relevant BMPs for the Project are described in detail in Appendix A, *Best Management Practices and Santa Clara Valley Habitat Plan Conditions, Avoidance and Minimization Measures, and Mitigation Measures Incorporated in the Project*. VHP Condition 7 would apply to aesthetics. BMPs relevant to the aesthetics analysis include the following:

> **REVEG-1:** Seeding – would require that restored areas are planted with native seeds as soon as work activities are complete
>
> **REVEG-2:** Planting Material – would require that restored areas are replanted with locally collected native species and that species selection is based on surveys of natural areas on the same creek that have a similar ecological setting
>
> **BI-8:** Choose Local Ecotypes of Native Plants and Appropriate Erosion-Control Seed Mixes – would require that restored areas are planted with native species that are ecologically appropriate to the work area and help improve visual conditions post-construction
>
> **WQ-11:** Maintain Clean Conditions at Work Sites – would require that work areas and access roads are maintained in an orderly condition and that materials or equipment left on site overnight are stored as inconspicuously as possible

VHP conditions were developed to help covered activities meet regional avoidance and minimization goals. VHP Condition 7, Rural Development Design and Construction Requirements, describes requirements for any new development that occurs outside the urban service area at the time the development is permitted under the Plan and for capital projects implemented by Permittees outside the urban service area. Requirements under Condition 7 relate to vegetation planting, light and glare, and restoration of disturbed areas.

Table 3.1-1 shows the applicability of each BMP to each Project impact.

Table 3.1-1. Valley Water BMPs Applicable for each Project Impact Related to Aesthetics

BMP	AES-1	AES-2	AES-3
REVEG-1: Seeding		X ~~ü~~	~~–~~
REVEG-2: Planting Material		X ~~ü~~	~~–~~
BI-8: Choose Local Ecotypes of Native Plants and Appropriate Erosion Control Seed Mixes		X ü	
WQ-11: Maintain Clean Conditions at Work Sites		X ~~ü~~	~~–~~

Table 3.1-2 shows the applicability of the VHP Condition 7 to each Project impact.

Table 3.1-2. VHP Condition 7 Applicable for each Project Impact Related to Aesthetics

VHP Condition	AES-1	AES-2	AES-3
VHP Condition 7		X ~~ü~~	X ~~ü~~

Table 3.1-3 shows the applicability of each VHP AMM to each Project impact.

Table 3.1-3. VHP AMMs Applicable for Each Project Impact Related to Aesthetics

AMM	AES-1	AES-2	AES-3
Aquatic 40: Maintain native shrubs, trees and groundcover whenever possible and revegetate disturbed areas with local native or non-invasive plants		X ü	
Aquatic 71: Preserve existing vegetation to the extent possible		X ~~ü~~	_ ~~–~~
Aquatic 103: All disturbed soils will be revegetated with native plants and/or grasses or sterile nonnative species suitable for the altered soil conditions upon completion of construction.		X ~~ü~~	_ ~~–~~

3.1.4.8 Thresholds of Significance

For the purposes of this analysis, the Project would result in a significant impact on aesthetics if it would:

AES-1: Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a State Scenic Highway (criterion b)

AES-2: In non-urbanized areas, substantially degrade the existing visual character or quality of public views of the site and its surroundings (public views are those that are experienced from publicly accessible vantage point) (criterion c)

AES-3: Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area (criterion d)

For AES-2 (criterion c), as described in **Section 3.1.5**, the Project is located in non-urbanized areas. For this reason, the impact analysis focuses on substantial adverse impacts of the existing visual character or quality of public views of the site and its surroundings. *CEQA Guidelines* criterion c also suggests that if a project is located in an urbanized area, then conflicts with applicable zoning and other regulations governing scenic quality may be a significant impact; however, since the Project is not in an urbanized area, Impact AES-2 does not analyze this part of the significance threshold.

Issues Dismissed from Further Review

CEQA Guidelines Appendix G suggests that a project may have a significant effect on aesthetics if it would have a substantial adverse effect on a scenic vista (criterion a). As described in the IS (Appendix B), a *scenic vista* is defined as a viewpoint that provides expansive views of a highly valued landscape for the benefit of the general public. Anderson Dam and Reservoir and the remainder of the study area may provide scenic views to people near the Project Area, but the dam and reservoir and the remainder of the study area do not include expansive, remarkable landscape elements that create scenic vistas. In addition, the Project Area is not designated as a scenic vista under Caltrans' Scenic Route Program (Caltrans 2024 ~~2018~~), Envision San José 2040 General Plan (City of San José 2023 ~~2011~~), City of Morgan Hill General Plan (City of Morgan Hill 2017 ~~2016~~), or the Santa Clara County General Plan (County 1994). Therefore, this impact would be less than significant, and it is dismissed from further analysis in this EIR.

Lead agencies have discretion to determine that only impairment of public views, and not private views from a few residences, would be considered visual impacts that could be significant. Therefore, this impact analysis does not consider changes to private views. ~~*CEQA Guidelines* criterion c suggests that if a project is located in an urban area, then conflicts with applicable zoning and other regulations governing scenic quality may be a significant impact; however, since the Project is not in an urbanized area, Impact AES-2 does not analyze this part of the significance threshold.~~

The Project would not result in substantial damage to rock outcroppings or to historic buildings. Impacts to these types of scenic resources are, therefore, not analyzed further in this impact analysis.

3.1.5 Impact Analysis

Impact AES-1: Substantial damage to scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway **(Less than Significant)**

No highways located in the vicinity of the study area are designated as a State Scenic Highway (Caltrans 2021b). While East Dunne Avenue is identified as a scenic rural route on Santa Clara County General Plan's Regional Parks and Scenic Highways map (County of Santa Clara 2008), views from this road mainly consist of the southeastern portion of Anderson Reservoir, and the Project Area is not visible. Similarly, although US 101 is identified as a rural scenic corridor in the Envision San José 2040 General Plan (City of San José 2023 ~~2011~~), views of the Project Area from the roadway are largely obscured by vegetation, and are limited to the Coyote Percolation Dam CM. While Anderson Dam is visible from US 101 from a distance through south County, the Project Area for the Seismic Retrofit components is approximately two miles from the roadway and divided by the City of Morgan Hill development. The Project would not result in substantial damage to rock outcroppings or to historic buildings. Impacts to these types of scenic resources are, therefore, not analyzed further in this impact analysis.

Regarding the other types of scenic resources noted in the *Regulatory Setting*, the Santa Clara County General Plan considers existing parks and trails in the study area to be scenic resources; impacts to parks and trails are evaluated in Impact AES-2. Similarly, the Project's visual effects associated with excavating and restoring the BHBA, which includes rock and other earthen materials, are described below in Impact AES-2. Additionally, potential impacts to public views associated with removal of vegetation, and trees in the Project Area are evaluated in Impact AES-2.

Significance Conclusion Summary

Based on the above summary, Project impacts on scenic resources other than those evaluated in Impact AES-2 would be **less than significant.**

Mitigation Measures

No mitigation is required.

Impact AES-2: Substantial degradation of the existing visual character or quality of public views of the site and its surroundings (Significant and Unavoidable)

Project construction would result in both temporary and permanent impacts on the visual character and quality of public views of the Project Area and its surrounding landscapes, as described below. The Project Area is located in a non-urbanized area. Therefore, the following analysis focuses on the Project's effects on the existing visual character or quality of public views of the site and the surrounding landscapes.

Seismic Retrofit Construction

Seismic Retrofit construction activities would result in temporary aesthetic impacts affecting the existing visual character and quality of public views. Project construction activities associated with the Seismic Retrofit component would occur within Anderson Lake County Park. The Live Oak Picnic Area, former Toyon Group Picnic Area, Anderson Lake Boat Ramp and Parking Area, and other park areas located south, west, and east of the dam would be used for temporary construction staging. Views of these areas would include construction equipment, stockpiled materials, construction fencing, vehicles, and active work areas. Aside from the Rosendin Park Area, a~~A~~ll the park areas located within the study area would be closed to public use throughout the duration of Seismic Retrofit construction. The Rosendin Park Area would be fully closed for 3 to 4 months during the initial blasting phase of construction and would partially reopen following this period with the exceptions of Lakeview, Gray Pine, Cochrane, and Rosendin Trails, which would all remain closed for the duration of blasting in Years 4, 5, and/or 6. There would be no planned closures of Rosendin Park Area before Year 4 or after Year 6 of Project construction. Therefore, in most locations, ~~no~~ park users would not have public views of construction areas, aside from within the Rosendin Park Area, where park users would have limited views of construction areas during certain periods of construction.

Within the Borello Ranch Estates, located west of the Live Oak Picnic Area, motorist views from public roadways would include views of active construction on Anderson Dam, in addition to construction staging within the park. Within the Holiday Lake Estates community, sporadic motorist views from public roadways would include in-reservoir activities (i.e., transport and stockpiling of earthen materials). Motorists on Cochrane Road to the west of the dam would also have varying degrees of views of the Seismic Retrofit construction. Recreators near the construction area on Coyote Creek Parkway would also have varying degrees of views of the Seismic Retrofit construction.

In addition, Seismic Retrofit construction would result in permanent impacts on visual resources in areas where public views of visual resources would be permanently changed, and the visual character and quality would be negatively affected.

The Seismic Retrofit construction activities and associated visual impacts are described below.

Tree Removal (Year 1)

As described in Chapter 2, *Project Description*, tree and vegetation removal would be necessary within the Project Area, including the BHBA and Staging Area 1, which is located in the existing Live Oak Picnic Area. **Table 3.1-4** shows the approximate number of mature, healthy native trees that would be removed for construction of the Seismic Retrofit component by Project feature.

Table 3.1-4. Approximate Number of Mature, Healthy Native Trees to be Removed for the Seismic Retrofit Component

Project Feature	Number of Mature, Healthy Native Trees
Staging Area 1	290
BHBA	270
Coyote Road realignment and access road construction	50
Rosendin Park area trails	20
Between the dam face and the spillway and in the vicinity of the unlined portion of the spillway	40

Based on a site assessment and as shown in **Table 3.1-4**, approximately 270 mature, healthy native trees would be removed at the BHBA. (Rottenborn pers. comm., 2022). Since the portion of Coyote Road along the dam crest and the boat ramp parking lot would be closed, no close-up public views of the tree removal at the BHBA would be accessible from these areas during the Seismic Retrofit construction. The loss of trees and vegetation, among other construction activities at the BHBA, would be visible from the Rosendin Park Area and, from a distance, at the Live Oak Picnic Area and public roadways within residential developments to the south and west of Cochrane Road**,** as shown in **Figure 3.1-4** (Photos 2, 4, and 12). ~~The BHBA viewer exposure, viewer concern, and visual sensitivity from recreators. Views of the BHBA from the Rosendin Park area would be limited during construction because the Rosendin Park area would be largely closed to recreators (i.e., all trails except for the Rancho Laguna Seca Trail and the Cochrane Trail, which would be dead-end trails with a turnaround at the construction site).~~ After construction is complete, views of the former BHBA would be unrestricted from the Rosendin Park area. The visual character of the BHBA and the visual quality is moderate to high. Because of the visual quality rating and large number of mature, healthy native trees that would be removed from County-owned parkland, tree removal at the BHBA would result in a significant impact to a scenic resource. Because the Project would remove not only the trees but also the hill on which they are growing and pave over the resulting lowered elevation with parking, no mitigation is available to reduce the impact of this tree removal. The impact on visual character and public views of the BHBA would be significant and unavoidable.

As shown in **Table 3.1-4**, during the construction phase, approximately 290 mature, healthy native trees would be removed in the vicinity of Staging Area 1. (Rottenborn pers. comm., 2022). Since the Live Oak Picnic Area and Serpentine Trail would be closed throughout the construction period, removal of trees at these locations would not be visible from public vantage points within these recreational areas during the Seismic Retrofit component construction. Some tree removal work from County-owned parkland, among other construction activities at Staging Area

1 at Live Oak Picnic Area, would be visible from public roadways within residential developments near Cochrane Road. Valley Water would retain trees along the north bank of the South Channel of Coyote Creek, which would partially screen views of removed trees at Staging Area 1 from Cochrane Road. **Figure 3.1-4** (Photos 10 and 11) show typical views of mature trees under the existing conditions baseline within the Live Oak Picnic Area.

With implementation of Valley Water BMPs REVEG-1 (Seeding), REVEG-2 (Planting Material), and BI-8 (Choose Local Ecotypes of Native Plants and Appropriate Erosion-Control Seed Mixes) at Staging Area 1 and adherence to requirements of VHP Condition 7, and AMMs Aquatic 40, Aquatic 71, and Aquatic 103, restored areas would be planted with native species that are similar in size and type to those removed. Over time, these BMPs would improve visual conditions in areas where vegetation removal is required during Project construction. Once construction is completed, and the use of the Live Oak Picnic Area is restored to the public, the removal of mature healthy trees along the south bank of the Coyote Creek riparian corridor (as shown in Photo 10 of **Figure 3.1-4**) would be perceived as a substantial adverse effect on scenic resources. Recreators (e.g., picnickers) at this viewpoint have longer duration views of the creek and riparian trees. Viewer exposure, viewer concern, and visual sensitivity of recreators that would use this site are high, and the visual character of Live Oak Picnic Area is high. From this viewpoint, the visual quality is high.

Because of the visual quality rating and large number of mature, healthy native trees that would be removed from County-owned parkland, impacts on visual character and public views due to removal of mature, healthy native trees along Coyote Creek at the Live Oak Picnic Area would be significant. Implementation of **Mitigation Measure AES-1** would require native trees of similar size and type to be planted in the areas where removal of mature, healthy native trees has occurred and causes significant impacts on scenic resources. These plantings would occur near the areas where the trees are removed to the extent possible and in other locations near the Project Area. Implementation of this mitigation measure would reduce adverse impacts on scenic resources. However, because of the long period that it takes for young oak trees to grow to a size similar to the size of trees to be removed, even after implementation of this mitigation measure, the impact would be significant and unavoidable.

In addition to these tree removals, and as shown in **Table 3.1-4**, approximately 40 mature, healthy native trees would be removed the dam face and the spillway and near the unlined portion of the spillway, approximately 50 due to road realignment and construction of access roads, and approximately 20 at the Rancho Laguna Seca trail near the construction area. Some of these tree removals would be on County-owned parkland. In each of these separate areas, viewer exposure, viewer concern, and visual sensitivity are moderate to high, and visual character is moderate because the areas are typical of the Anderson Reservoir area. Visual quality is therefore moderate to high. The removal of these trees on County lands would be significant. Implementation of **Mitigation Measure AES-1** would require native trees of similar size and type to be planted in the areas where removal of mature, healthy native trees has occurred and causes significant impacts on scenic resources. These plantings would occur near the areas where the trees are removed to the extent possible and in other locations near the Project Area. Implementation of this mitigation measure would reduce adverse impacts on scenic resources. However, because of the long period that it takes for young oak trees to grow to a size similar to the size of trees to be removed, even after implementation of this mitigation measure, the impact would be significant and unavoidable.

The following sections describe visual impacts for selected activities occurring during construction aside from tree removal. The below analyses demonstrate that, aside from tree removal and activities at Staging Areas 1 and 4, tree removal and topography change at the BHBA, and tree removal at the Conservation Measure sites, construction activities would not cause substantial degradation of existing visual character or quality of public views.

Site Preparation (Year 1)

The first year of construction would include the mobilization and site preparation activities for staging areas, stockpile areas, and access roads. Based on the location of the staging and stockpile areas (most of which would be within the reservoir) (see **Figure 2-4**), construction equipment and site preparation activities within Anderson Lake County Park would not affect public recreator views from the Live Oak Picnic Area as these areas would be closed to the general public. However, recreator views from the Rosendin Park Area could be affected by site preparation activities, including the full dewatering of the reservoir, as discussed below.

The Live Oak Picnic Area (where Staging Area 1 would be viewable) and the boat parking lot (location of Staging Area 3) would be closed throughout the construction of the Project. No recreational views of these areas would be accessible. Construction equipment and site preparation activities within Staging Areas 1 and 4 would be partially visible from the public roadways within the Borello Ranch Estates and Cochrane Road, although mature trees retained would provide some visual screening. Pedestrians and residents along Cochrane Road may also have partial views of these three staging areas.

Full dewatering of the reservoir would expose recreators in the Rosendin Park Area to views of the lower water levels in the reservoir. However, under the Existing Conditions Baseline and typical reservoir operations during droughts, recreators using the Rosendin Park Area are already accustomed to similar conditions as a result of both the drought and construction of the FOCP, which required dewatering of the reservoir to deadpool. Views of barren banks and low water storage conditions would incrementally worsen during the Project's construction phase. Though views of the reservoir from the Rosendin Park Area would be degraded for the periods when recreators would have access to these views, these marginally modified views would be temporary until the Project activities are completed. Once the Project is completed, the reservoir water levels would return to normal operating conditions. Although viewer exposure, viewer concern, and visual sensitivity would be high, visual character is low, so visual quality would be low to moderate. Therefore, the impact from full dewatering of the reservoir on visual character and public views would be less than significant.

Site preparation activities at the Packwood Gravel Borrow Pit and the BHBA would also be visible to recreators in the Rosendin Park Area. Due to the temporary nature of these site preparation activities, there would be no substantial permanent change in visual character and public views and impacts would be less than significant. Additional construction activities that would be visible from the Rosendin Park Area, including excavation at the BHBA, are discussed further below under *Dam Excavation and Reconstruction (Including Excavation of Embankment Materials from Borrow Areas) and Raising Dam Crest (Years 2-6)* and *Completed Seismic Retrofit Components (Year 7).*

Staging Area 5 (located at 2100 San Pedro Avenue) would be used for construction worker parking. This area would be visible from San Pedro Avenue and Hill Road, both of which are public roadways used by residences.

Staging Area 6 (located at the Holiday Lake Estates Boat Ramp Parking Lot) would be used for mobilizing equipment, reservoir access, and stockpiling, and would be visible from Holiday~~s~~ Drive, a public roadway.

Construction equipment and worker vehicles using haul routes leading to the Project's staging areas would be visible to pedestrians and motorists located along Cochrane Road, Peet Road, and Half Road, as well as other smaller side streets near these roadways.

Stockpile areas~~, and~~ the use and construction of access roads, and the Reservoir Disposal Area would be largely unseen from public roadways throughout the construction of the Project. All Project staging areas are described in **Table 2-4**. Views from public roadways would be limited to the access road on the downstream slope of the dam connecting to the Anderson Dam Trail, continuing into Staging Area 1. This access road would be visible from Cochrane Road and roadways within the Borello Estates development. However, the viewer groups, pedestrians and motorists, that would have views of the access roads would have low viewer exposure, viewer concern, and visual sensitivity. Visual character of these visual resources varies from low to high. Visual quality would therefore be low to moderate. The impact on visual character and public views would be less than significant.

Construction of Temporary Water Diversion System (Year 2)

Due to the location of the temporary water diversion infrastructure, including the cofferdam, sediment check dams, reservoir bypass pipe, and temporary bypass pumping system, and the temporary closure of Anderson Lake County Park ~~and Rosendin Park~~, construction of the temporary water diversion system would largely be out of public view and obscured by existing mature vegetation and topography of the surrounding area. However, public views of limited portions of the temporary water diversion system, including the low-level outlet tunnel entrance, lake tap, and trash rack, would be visible from trails within the Rosendin Park Area, including the Lakeview Trail and Gray Pine Trail which would be open during Year 2 of Seismic Retrofit construction. Although viewer exposure, viewer concern, and visual sensitivity at these locations would be high, visual character is low due to the intervening topography and vegetation that would partially obstruct views of the temporary water diversion system, so visual quality would be low to moderate. Furthermore, views of the temporary water diversion system would be temporary and there would be no permanent change to recreator views. Therefore, the impact on visual character and public views from the Rosendin Park Area would be less than significant.

Similar to other construction phases, pedestrians and motorists using Cochrane Road, Peet Road, and Half Road would have views of construction equipment using the haul roads leading to the temporary water diversion system work area. However, the viewer groups that would have views of construction equipment on the haul roads would have low viewer exposure, viewer concern, and visual sensitivity. The visual quality would be low. The impact on visual character and public views would be less than significant.

Full Dewatering of the Reservoir (Years 2-6)

The full reservoir dewatering would involve dewatering activities that would reduce reservoir levels from deadpool to an elev. 450 feet, exposing approximately 1,420,000 cy of additional sediment. Due to the partial closure of Anderson Lake County Park during the construction period, public views of the dewatered reservoir would largely not be accessible (e.g., from the dam crest or boat launch) (Valley Water 2021 ~~2023~~). The Rosendin Park Area would be ~~largely~~ fully closed for 3 to 4 months during the initial blasting phase of construction and would partially reopen following this period with the exceptions of Lakeview, Gray Pine, Cochrane, and Rosendin Trails, which would all remain closed for the duration of blasting ~~(as described above under *Tree Removal [Year 1])* during Seismic Retrofit construction~~. Recreators using the ~~these~~ open trails in the Rosendin Park Area, ~~namely~~ which would include all the trails in Years 2 and 3, as well as the Rancho Laguna Seca Trail outside the 3 to 4 month initial blasting period in Year 4, 5, or 6, and any reopened sections of the Cochrane Trail after blasting during Years 4 through up to Year 6, would have views of the reservoir's lower water levels.

However, as discussed above, under the existing conditions baseline and typical reservoir operations during droughts, recreators using Rosendin Park are already accustomed to similar conditions as a result of both the drought and construction of the FOCP, which required dewatering of the reservoir to deadpool. Views of barren banks and low water storage conditions would incrementally worsen during the Project's construction phase. Though views of the reservoir from these trails would be degraded for ~~approximately 4 years of construction~~ the periods when recreators would have access to these views, these marginally modified views would be temporary until the Project activities are completed and they are typical of the existing conditions baseline. Once the Project is completed, the reservoir water levels would return to normal operating conditions. Although viewer exposure, viewer concern, and visual sensitivity would be high, visual character is low, so visual quality would be low to moderate. The impact from full dewatering of the reservoir on visual character and public views would be less than significant.

Dam Excavation and Reconstruction (Including Excavation of Embankment Materials from Borrow Areas) and Raising Dam Crest (Years 2-6)

As described in Chapter 2, dam excavation would begin during the dry season (April through November) of Year 2, and would continue throughout Years 3 and 4, followed by the reconstruction of the dam over Years 5 and 6. Excavation of the dam would involve substantial earth movement and vegetation removal and the hauling of excavated materials from the dam to in-reservoir stockpile areas and the Reservoir Disposal Area (see **Table 2-9** through **Table 2-14** in Chapter 2). During the dam excavation phase, a temporary tie-back wall would be installed along a 400-foot-long segment of Cochrane Road at the toe of the dam. This wall would be a soil nail[1] and shotcrete wall[2] that would rise 50 feet high above the Stage 1B Excavation grade.

Reconstructing the dam would require using material stored in the stockpile areas and material excavated from both the Packwood Gravel Borrow Pit and BHBA. The Packwood Gravel Borrow Pit is located on the eastern side of the reservoir and would ~~only~~ be visible from trails within the Rosendin Park Area, which would be partially ~~largely~~ closed during blasting in Years 4, 5, and/or 6 ~~throughout Project construction (as described above under *Tree Removal (Year 1)*.~~ The BHBA is located southeast of the parking area at the left end of the existing dam. As described in Chapter 2, *Project Description,* approximately 1,420,000 cy of material would be excavated from the BHBA using drilling and blasting methods to break up the rock. **Figure 2-4** shows the area of material that would be excavated.

With the exception of the Rosendin Park Area, which would be fully closed for 3 to 4 months during the initial blasting phase of construction and would partially reopen following this period with the exceptions of Lakeview, Gray Pine, Cochrane, and Rosendin Trails, which would all remain closed for the duration of blasting ~~largely closed throughout Project construction~~, construction equipment and activities associated with these work phases would not be visible within most of Anderson Lake County Park due to park closure (**Figure 3.1-4,** Photo 1 and Photo 2). From trails within the Rosendin Park Area, recreators would have limited views of excavation activities at the dam and the Packwood Gravel Borrow Pit (**Figure 3.1-4**, Photo 3), haul trucks transporting material to and from stockpile areas and the Reservoir Disposal area, and dam reconstruction. Recreators would have more immediate views of construction activities at the BHBA (**Figure 3.1-4**, Photo 4). While recreators in the Rosendin Park Area would be accustomed to viewing construction activities associated with the FOCP, proposed construction activities would further degrade these views as the Project would result in more extensive ground-disturbing activities. Recreators in the Rosendin Park Area may also have temporary views of ~~Stockpile Area D and~~ the Reservoir Disposal Area throughout the dam excavation phase. Implementation of BMP WQ-11 (Maintain Clean Conditions at Work Sites) would require these work areas are kept clean to help reduce adverse effects on views from the Rosendin Park Area. Most of these activities would not have a substantial change in visual character and public views. However, excavation at the BHBA would remove the hill that is currently at that location and pave over it with parking. This change is discussed below under *Completed Seismic Retrofit Components (Year 7)*.

Excavation of the existing dam; blasting, drilling and excavation activities conducted at BHBA; and reconstruction of the new dam embankment would be visible from areas located outside the park to the west of the dam. Distant views of these activities and large equipment including large bulldozers, graders, loaders, and dump trucks may be seen by motorists from US 101, Cochrane Road, Peet Road, and residential side streets to the west of the dam. Most of these views are 0.5 miles or greater from the dam itself and may also be limited by existing vegetation

[1] Soil nail wall construction is a technique typically used to stabilize soils in an area where landslide is a concern. Soil nail walls can prevent landslides by inserting steel reinforcement bars into the soil and anchoring them into the soil strata.
[2] Shotcrete wall construction is a technique involving wet- or dry-mix concrete that is pneumatically projected at high velocity through a hose and nozzle on a surface to achieve consolidation.

and intervening terrain. Due to distance, views of such construction activities would not result in a substantial visual disruption from these areas. The changes in views from these areas outside of the park would be temporary, although the changes would span approximately 6 years. Following project implementation, the Project Area other than BHBA would appear similar to under the existing conditions baseline; therefore, Project implementation would not substantially degrade the visual character or quality of public views.

The temporary tie-back wall along Cochrane Road would be visible from motorists on Cochrane Road. However, motorist views would be fleeting. Accordingly, motorists have low viewer concern, viewer exposure, and visual sensitivity. Visual quality would also be low. Therefore, Project implementation would not substantially degrade the visual character or visual quality of public views.

Other than removal of the hill at the BHBA, which would constitute a substantial permanent change to the local topography and which is discussed below, dam excavation and reconstruction activities would not result in a substantial change to visual character and quality of public views. Therefore, impacts on visual character and public views from dam excavation and reconstruction would be less than significant.

Construction of New Outlet Works and Spillway Modifications (Years 2-6)

Construction of the HLOW and LLOW on the northern side of the dam and spillway modifications would occur within Anderson Lake County Park. Views of these construction activities by the public would be largely obstructed due to mature vegetation and the natural topography of the area, as the park itself would be largely closed to public use. Partial views of construction activities associated with the new outlet works system may be visible from areas of the Rosendin Park Area during the periods in which the park would be open to recreators. ~~however, the park would also be largely closed throughout construction activities (as described above under *Tree Removal [Year 1]).*~~ Although viewer exposure, viewer concern, and visual sensitivity at these locations would be high, visual character is low due to the intervening topography and vegetation that would partially obstruct views of the HLOW and LLOW, so visual quality would be low to moderate. Furthermore, views of the construction of the HLOW and LLOW would be temporary and there would be no permanent change to recreator views as a result of the construction of the HLOW and LLOW. Therefore, the impact on visual character and public views from the Rosendin Park Areas would be less than significant. Views of the outlet structures downstream of the dam would be visible from Cochrane Road by motorists. Viewer exposure, viewer concern, and visual sensitivity would be low and visual character would be moderate. Therefore, visual quality would be low to moderate. Accordingly, impacts on visual character and public views from construction of new outlet works and spillway modifications would be less than significant.

Permanent Roads, Modifications to Boat Ramp Parking Lot and Other Recreational Facilities, and Site Restoration (Year 7)

Near the end of construction, permanent modifications would be made to Coyote Road along three segments, including (1) from the entrance kiosk to the dam crest, (2) across the dam crest, and (3) along the south side of the spillway. Access from Cochrane Road to the Anderson Dam toe would also be relocated. The Anderson Dam boat ramp parking area would be replaced and enlarged, and the existing boat ramp would be replaced and extended. Other recreational improvements that would be constructed include restoration of the Live Oak Picnic Area and replacing the Serpentine Trail with an access path extending from the Live Oak Picnic Area to the crest of Anderson Dam. Improvements at the Serpentine Trail would mostly follow the current alignment ~~but would include a pedestrian bridge crossing over the North Channel~~, where the North Channel weir that was installed during the FOCP would be visible. Lastly, site restoration activities would generally involve removing temporary facilities and restoring disturbed areas to their preconstruction conditions, including, but not limited to, stockpile areas, access roads, the check dams, staging areas. Activities would include regrading and vegetation planting. Because of borrow activities during construction, the BHBA would be greatly reduced in size, covered in concrete to provide slope stability, and paved for parking. This change at the BHBA would amount to a substantial change in topography and is discussed below under *Completed Seismic Retrofit Components (Year 7)*. Views of these Year 7 project components would not be visible to a large number of viewers, as the facilities would still be close to access. Viewer exposure, viewer concern, and visual sensitivity would be low and visual character would be moderate. Therefore, visual quality would be low to moderate. Accordingly, impacts on visual character and public views from construction of new outlet works and spillway modifications would be less than significant.

Similar to the other Seismic Retrofit components and work phases, recreators using trails in the Rosendin Park Area, which would be <u>partially</u> ~~largely~~ closed <u>during blasting in Years 4, 5, and/or 6</u> ~~(as described above under *Tree Removal (Year 1)*),~~ would have partial views of in-reservoir restoration activities and associated equipment, including the grading of stockpile areas. Recreators in the Rosendin Park Area would also have views of restoration activities that take place at the BHBA (e.g., placing soil on the benches and hydroseeding with grasses and shrubs, concrete placement). Downstream of the dam, motorists and pedestrians along Cochrane Road and other nearby residential side streets may have partial and distant views of the BHBA restoration activities and restoration activities occurring at Staging Areas 1 and 4. The Project's road, recreational facility modifications, and site restoration activities would be visible at varying degrees from the Rosendin Park <u>Area</u> and public roadways within residential developments downstream of the dam. Implementation of Valley Water BMPs REVEG-1 (Seeding), REVEG-2 (Planting Material), BI-8 (Choose Local Ecotypes of Native Plants and Appropriate Erosion-Control Seed Mixes), and VHP Condition 7, and AMMs Aquatic 40 Aquatic 71 and Aquatic 103 would require seeding and revegetation of disturbed areas and that an ecologically appropriate seed mix is applied to revegetated areas. With adherence to requirements of applicable VMPs and VHP AMMs, the impact from degradation of visual character or quality of public views from permanent roads, modifications to boat ramp parking lot and other recreational facilities, and site restoration would be less than significant.

Completed Seismic Retrofit Components (Year 7)

Following the completion of the Seismic Retrofit construction activities, Anderson Lake County Park would be <u>fully</u> open to the public. Several of the post-construction operations would be visible to sensitive viewers, but the Project would not substantially degrade the visual character or quality of public views of the Project Area, as the area would return to near pre-FOCP conditions (i.e., Pre-FERC Order Conditions Baseline) over time. Specific Project components that would result in permanent visual changes include the replaced dam embankment, raised dam crest, spillway replacement, the new outlet works system, the BHBA, permanent roadway modifications, and recreational facility modifications. The long-term and/or permanent visual changes associated with these project components are described in the paragraphs below.

Replaced Dam Embankment, Raised Dam Crest, and Spillway

Once Project construction is completed, the replacement dam would be larger than the existing facility. As described in Chapter 2*, Project Description*, the dam crest would be raised by approximately 9 feet and the length would be approximately 280 feet longer than the existing dam. The new spillway would be located within the same footprint occupied by the existing spillway and would have the same crest elevation. In general, while the new dam would be slightly taller and longer, these modifications would be similar in nature to the existing dam and would not appear substantially different from the existing facilities. Views of the dam embankment would not be substantially different than those shown in Pre-FERC Order Conditions Baseline photos (**Figure 3.1-3** ~~**Figure 3.1-2**~~). Furthermore, the replacement dam and spillway would not substantially degrade public views or the visual character or quality of views within Anderson Lake County Park or the surrounding area. The impact on visual character and public views would be less than significant.

Outlet Works

The new outlet works system would replace the existing outlet works and be comprised of the HLOW and LLOW facilities. The HLOW system's outlet structure would be comprised of two 11-foot-diameter fixed-cone valves and an energy dissipation structure. The outlet structure associated with the LLOW outlet system would include a 42-inch-diameter sleeve and valve, a 54-inch-diameter cone valve with a concrete-enclosed dissipation chamber and stilling basin, and riprap slope on the north bank of Coyote Creek. The LLOW would be approximately 200 feet downstream of the current outlet to Coyote Creek in the former Toyon Group Picnic Area. This facility may be partially visible from Cochrane Road and, while these facilities would be larger than the existing outlet works, these facilities would be visually consistent with the existing outlet works and therefore would not substantially degrade public views or the visual character and quality of this particular area. The impact on visual character and public views would be less than significant.

Basalt Hill Borrow Area

As described in the *Dam Excavation and Reconstruction (Including Excavation of Embankment Materials from Borrow Areas)* analysis above, the Project would involve removing a large portion of the hill at the BHBA (western side) within a 0.9-acres area. The final grade of the borrow area would be elev. 670 (the same level as the current boat launch parking lot). The excavated portion of the BHBA would be graded, and the lower portion would be terraced, fronted by a combination of rock dowels and shotcrete along the excavated surface. The lower portion would have a steeper slope of 0.8:1 (horizontal : vertical) and a more gradual slope of 1.6:1 near the top of the hill. Additionally, the benches would be restored with 1-2 feet of loose soil material and hydroseeding. A portion of the area would also be paved for parking. The shotcrete wall segments (which would have a gray or brown tone) and benches along the excavated slope would be most clearly visible to recreators using the boat ramp parking lot, and partially visible from the Rosendin Park Area. Immediate views of the restored BHBA would be visible to recreators, who have high viewer exposure, viewer concern, and visual sensitivity. More distant views of the restored BHBA would be accessible from local public roads to the west of the dam, though visibility would vary outside of the park due to viewing distance, existing terrain, and vegetation. These viewers would have low viewer exposure, viewer concern, and visual sensitivity.

After construction is completed, the shotcrete may appear more pronounced as this would introduce a more developed component to the overall landscape. Over time, as the grasses and shrubs within the restored slope mature, the hillside would appear more natural and visually consistent with the hills surrounding the Project Area.

However, removal of the hill at the BHBA would constitute a substantial permanent change to the local topography in an area where viewer concern, viewer exposure, and visual sensitivity are high (to recreators), visual character is moderate, and visual quality is moderate to high. Therefore, impacts on visual character and public views from changes in topography at the BHBA would be significant. No mitigation is available to reduce the level of mitigation; therefore, the impact would be significant and unavoidable.

Permanent Roadway and Recreational Facility Modifications

As described in Chapter 2*, Project Description,* and in the section above, existing roadways throughout the Project Area would be permanently modified. Permanent roadway modifications would occur from Coyote Road through the boat ramp parking area, Coyote Road across the dam crest, Coyote Road along the spillway, access roads leading to the parking areas at the base of the dam, and a permanent access road to the left bank of the North Channel downstream of the dam. Coyote Road across the dam crest would be publicly accessible by pedestrians but not vehicles following Seismic Retrofit construction ~~in these areas would be no longer be publicly accessible~~.

As part of the Project, several of the recreation areas and facilities within Anderson Lake County Park would be permanently closed or modified. Recreational facilities that would be modified as part of the Project include Anderson Lake boat ramp and parking area, Live Oak Picnic Area, and Serpentine Trail. During Years 1 through 7 ~~8~~ of Seismic Retrofit construction, the existing Anderson Lake Boat Ramp and Parking Lot would be temporarily closed and improved. The improved Anderson Boat Ramp and Parking Area would be larger than the existing facilities. The parking area would be constructed up to 10 feet above the existing parking area over the former BHBA (discussed above under “Basalt Hill Borrow Area”). Restoration of the boat ramp parking area would include grading, replacement of curb and gutter, repaving, restriping, reinstallation of lighting, planters, irrigation, revegetation, and the replacement or refurbishment of the park bathroom facility.

Other recreational improvements include restoring the Live Oak Picnic Area and replacing the Serpentine Trail with an access path extending from the Live Oak Picnic Area to the crest of Anderson Dam. Following Project construction, all impacted park features would be replaced onsite and in-kind (40 picnic tables, eight BBQ grills, a fee station, a pay phone, a pet waste station, ~~a pedestrian bridge,~~ a 0.25 miles walking loop, 78 regular parking spaces, five ADA parking spaces, restrooms, and a group picnic area with eight tables, a large BBQ, and a food preparation table). Post-construction restoration of the Live Oak Picnic Area would also include park enhancements in the areas of the park adjacent to Coyote Creek. Views of the modified roads would be consistent with those under the existing conditions baseline and would exhibit design qualities and characteristics similar to the existing roads. While the re-configured Serpentine Trail would be different from under the existing conditions baseline, these recreational facilities would be visually consistent with existing facilities. As restored vegetation that is installed at these areas matures, the visual character would return and be consistent with the surrounding landscape; however, this would take several years. Changes to Live Oak Picnic

Area are discussed above under *Tree Removal (Year 1)*. Because, other than Live Oak Picnic Area, the areas would be restored to a condition near the existing conditions baseline over time, these components would not substantially degrade the visual character or quality of public views. The impact on visual character and public views would be less than significant.

Summary of Seismic Retrofit Construction Activities Impacts

Viewers near the study area have become accustomed to the FOCP construction activities occurring within the Project Area; therefore, their viewer concern and visual sensitivity relating changes due to FOCP would be low. However, the extent of Seismic Retrofit construction activities would encompass a larger area and occur over a longer duration than FOCP, temporarily disrupting public views from the Rosendin Park Area and from local public roadways to the west of the dam, including Cochrane Road. The dewatered reservoir and Stockpile Area K would also be visible from roads in the Holiday Estates development. Implementation of BMP WQ-11 (Maintain Clean Conditions at Work Sites) would require that work areas and access roads are maintained in an orderly condition to the extent feasible and that materials or equipment left onsite overnight are stored as inconspicuously as possible. Valley Water BMPs REVEG-1 (Seeding), REVEG-2 (Planting Material), BI-8 (Choose Local Ecotypes of Native Plants and Appropriate Erosion-Control Seed Mixes), and VHP Condition 7, and AMMs Aquatic 40, Aquatic 71, and Aquatic 103 would require seeding and revegetation of disturbed areas and that an ecologically appropriate seed mix is applied to revegetated areas.

While these measures would help reduce temporary adverse effects on views of the Project Area, as noted above in the discussion of the Seismic Retrofit Construction, *Tree Removal (Year* 1*)*, the removal of mature, healthy native trees that occur along Coyote Creek at the Live Oak Picnic Area~~, Ogier Ponds, and the North Channel Extension~~ would create visual disruption that would not be fully restored for a period of 20 years or more as the replacement trees mature. Also, the high visibility of Staging Areas 1 and 4 to recreators, coupled with the activity and change in topography at the BHBA would also create strong permanent visual disruption. These impacts would be significant because public views of portions of these areas would be substantially degraded. Implementation of **Mitigation Measure AES-1** would require replacement of mature, healthy trees that are removed along Coyote Creek at the Live Oak Picnic Area ~~and North Channel Extension.~~ Although this mitigation measure would reduce the impact, it would not reduce to less than significant. Therefore, the impact would be significant and unavoidable.

The BHBA would appear largely modified as a result of extensive excavation. Mature, healthy native trees would be removed, and the topography would be substantially changed when the hilltop is removed during excavation of the borrow materials. The restored hill at the BHBA would be stabilized by a combination of shotcrete and rock dowels and grasses and shrub plantings installed on the benches. Despite the restoration, the topography of the hillside would appear different than under the existing conditions baseline, and trees would have been removed. Because public views of the restored hillside would include recreator views from the Rosendin Park Area ~~area~~, the changed topography would result in a significant impact on visual character and public views. No mitigation is available to reduce the impact, so that impact would be significant and unavoidable.

In addition, implementation of **Mitigation Measure AES-2** would screen portions of Staging Areas 1 and 4 from pedestrians and motorists using Cochrane Road and would prevent the substantial degradation of public views of these staging areas. This measure would reduce this impact to a less than significant level with mitigation.

Based on the discussions above, most Seismic Retrofit components, including the replaced dam embankment, raised dam crest and spillway, new outlet works, permanent roadway and recreational facility modifications would be similar in character to the existing facilities and would not substantially degrade visual character and public views of the Project Area. However, tree removal at Live Oak Picnic Area~~, the North Channel Extension~~, and the BHBA, and changes in topography at the BHBA would substantially degrade visual character and public views.

In summary, even with implementation of **Mitigation Measure AES-1 and AES-2**, construction and completion of the Seismic Retrofit components would result in a significant and unavoidable impact on the existing visual character and quality of public views.

Conservation Measures Construction

Impacts related to the visual character and quality of public views near the Ogier Ponds CM, the Phase 2 Coyote Percolation Dam CM, Maintenance of the North Channel Reach ~~Extension~~, and the Live Oak Restoration Reach Project Area are described below. The visual character and quality of public views associated with other Conservation Measures involving construction of habitat enhancements (e.g., in-stream restoration, placement of woody debris, and/or gravel augmentation) are also provided at the end of this section.

Several of the Conservation Measures would involve removal of mature, healthy native trees. **Table 3.1-5** shows the approximate number of mature, healthy native trees that would be removed for construction of the Conservation Measures component by Project feature. Conservation Measures not described in **Table 3.1-5** would not involve removal of mature, healthy native trees.

Table 3.1-5. Approximate Number of Mature, Healthy Native Trees to be Removed for the Conservation Measures Component

Project Feature	Number of Mature, Healthy Native Trees
Ogier Ponds	40
~~North Channel Extension~~	~~30~~

Ogier Ponds CM

As described in Chapter 2, *Project Description*, the Ogier Ponds CM would separate Coyote Creek from Ogier Ponds. The construction activities associated with this Conservation Measure would include the staging of equipment and materials, removal of trees, including approximately 40 mature, healthy native trees (see **Table 3.1-5**), and operation of equipment near Coyote Creek Trail. Viewer exposure, viewer concern, and visual sensitivity to the Ogier Ponds resource would be moderate to high. As described in *Environmental Setting*, visual character and visual quality are moderate.

Since the Coyote Creek Trail offers scenic viewing opportunities for recreators, these construction activities may be visible from the Coyote Creek Trail; however, these activities would be temporary and limited to the 3-year construction period (occurring primarily between

June and October annually). ~~However, portions of the Coyote Creek Trail adjacent to the work area would be closed throughout the duration of the construction phase. Therefore, recreators using Coyote Creek Trail would not have close-up views of work activities. Trail detours would be provided for recreators around the Project Area; therefore, views of the study area from a distance would be possible.~~ Once Ogier Ponds construction activities are completed, open water habitat would be reduced by filling Ponds 1 and 5 ~~(15 acres)~~ and partially filling Ponds 2 ~~(4 acres of fill)~~ and 4 ~~5 (1 acre of fill)~~, converting approximately 19 acres of existing open water and wetlands habitat at Ponds 1, 2, 4, and 5 to creek channel and connected floodplain habitat. About 25 acres of existing uplands would be converted to channel and floodplain habitat. ~~This Conservation Measure would also restore~~ Coyote Creek and the adjoining floodplain would be ~~with~~ planted with native vegetation, trees, and aquatic features, including large woody debris structures. Recreators accustomed to viewing open water from the Coyote Creek Trail would notice the reduction in open water habitat with the removal of approximately 40 mature native trees from County-owned parkland for this work. As discussed above under *Tree Removal*, removal of mature trees in areas that are publicly viewable by recreators would be perceived as a substantial adverse effect on scenic resources. Therefore, removal of mature trees required during construction of the Ogier Ponds CM would degrade the visual character and quality of the visual resource and would accordingly constitute a significant impact. Implementation of **Mitigation Measure AES-1** would replace mature, healthy trees that are removed for CM construction with similar but younger trees. Views of riparian vegetation and planted trees would mature over time and appear visually consistent with riparian vegetation commonly seen throughout the Coyote Creek Parkway. Implementation of this mitigation measure would reduce adverse impacts on scenic resources. However, because of the long period that it takes for young oak trees to grow to a size similar to the size of trees to be removed, even after implementation of this mitigation measure, the impact would be significant and unavoidable.

Phase 2 Coyote Percolation Dam CM

As described in Chapter 2, *Project Description*, the Phase 2 Coyote Percolation Dam CM would require the temporary closure of work areas near the Coyote Percolation Dam. Viewer exposure, viewer concern, and visual sensitivity to the Phase 2 Coyote Percolation Dam CM resource would be moderate. As described in *Environmental Setting*, visual character and visual quality are moderate.

Views of the construction work area and equipment would be visible from the Coyote Creek Trail. This construction would also be visible from the access point along Metcalf Road. Within the construction area, enhancements would occur on the concrete foundation sill of the dam itself, as well as within a portion of the downstream approach of the channel. Vegetation removal would be limited, as the work area is largely within the creek channel, and construction vehicles have previously accessed the work area through FOCP construction activities. No removal of mature, healthy native trees is anticipated. Following construction, the enhanced channel would appear similar to the existing conditions baseline. Therefore, construction would not substantially degrade the visual character or quality of public views of this area. Impacts would be less than significant.

Maintenance of the North Channel Reach ~~Extension~~

As part of the Project, the wetland bench in the North Channel area would be maintained, restoration plantings would be conducted and flow capacity in the North Channel Reach would be maintained. These maintenance activities would occur during Project construction but would involve limited changes to public views as they would preserve existing conditions within the North Channel Reach during Project construction.

~~As part of the Project, the North Channel Extension would be constructed to restore the historic North Channel of Coyote Creek. Construction of the North Channel Extension would involve grading a new channel from downstream of the North Channel weir to the historic confluence of the North Channel with the South Channel of Coyote Creek. The grading process would require removal of vegetation and 30 mature, healthy native trees (see **Table 3.1-5**) from County-owned parkland, removal of placed boulder material to create the existing break in the North Channel, and restoration of the historic channel to support the flow of the creek downstream. Viewer exposure, viewer concern, and visual sensitivity to the Ogier Ponds resource would be moderate to high. As described in *Environmental Setting*, visual character and visual quality are moderate.~~

~~As described in Chapter 2, *Project Description*, construction activities associated with the North Channel Extension and habitat enhancement would occur during the dry season of Construction Year 1, when Live Oak Park has been prepared for construction staging for Seismic Retrofit of Anderson Dam. Because the staging area would shield views of construction of the North Channel Extension, its construction would not be visible to recreators on Coyote Creek Trail or motorists on Cochrane Road, because views of this work would be screened through the staging area occupying Live Oak Picnic Area.~~

~~After construction is complete, there would be public views of the North Channel Extension from Cochrane Road and Live Oak Picnic Area. Following grading activities, the work area would be restored along the banks with native trees and vegetation, in accordance with Valley Water BMPs REVEG-1 (Seeding), REVEG-2 (Planting Material), BI-8 (Choose Local Ecotypes of Native Plants and Appropriate Erosion-Control Seed Mixes), and VHP Condition 7, and AMMs Aquatic 40, Aquatic 71, and Aquatic 103, which would require the seeding and revegetation of disturbed areas, and that an ecologically appropriate seed mix is applied to revegetated areas and native vegetation and trees are planted according to tree replacement ratios presented in **Mitigation Measure AES-1**. However, despite revegetation that would take place under Valley Water BMPs and VHP conditions, and AMMs, recreators using Live Oak Park after construction is complete would have a view of the area at the North Channel Extension site where approximately 30 mature, healthy native trees had been removed. As discussed above under *Tree Removal (Year 1)*, removal of mature trees in areas that are publicly viewable by recreators would be perceived as a substantial adverse effect on scenic resources. Therefore, removal of mature trees required during construction of the North Channel Extension would degrade the visual character and quality of the visual resource and would accordingly constitute a significant impact. Implementation of **Mitigation Measure AES-1** would require native trees to be planted in areas where removal of mature, healthy native trees has occurred and caused significant impacts on scenic resources. Implementation of this mitigation measure would reduce adverse impacts on scenic resources. However, because of the long period that it takes for young oak trees to grow to a size similar to the size of trees to be removed, even after implementation of this mitigation measure, the impact would be significant and unavoidable.~~

Maintenance Activities at the Live Oak Restoration Reach and Sediment Augmentation Program

Conservation Measures related to spawning gravel and rearing habitat improvements, including implementation of the Sediment Augmentation Program and the installation of large woody debris in Coyote Creek, may require short-term closures of the Coyote Creek Trail, limiting views of those work areas. The visual disruptions to recreators during the construction phase would be temporary and short in duration. Depending on the public visibility of the sites, placement of spawning gravel and improvement of rearing habitat would incrementally improve viewing conditions or would not result in a substantial visual change as natural habitats along the creek corridor are restored. For these reasons, Conservation Measures involving habitat enhancements on Coyote Creek would have a less-than-significant impact on public views and the visual character and quality of the sites and surrounding areas.

Post-Construction Anderson Dam Facilities Operations

Once the Seismic Retrofit components are complete, water levels in Anderson Reservoir would return to unrestricted capacity, which would be higher under the post-construction reservoir operations ~~future conditions baseline~~ than the water levels under the Pre-FERC Order Conditions Baseline. As described in Chapter 2 *Project Description*, once the reservoir has been re-filled, the surface area would be approximately 1,250 acres at spillway crest level. Accordingly, under the post-construction reservoir operations ~~future conditions baseline~~, the visual character and quality of public views of the reservoir would improve. The viewer exposure and viewer concern of recreators of the reservoir are moderate to high, and as described in *Environmental Setting*, the visual character and quality of the reservoir are low to moderate. The viewer exposure and viewer concern of recreators of the Live Oak Picnic Area are high, and as described in *Environmental Setting*, the visual character and quality are moderate to high.

Recreational views of the reservoir would improve from multiple vantage points, including, but not limited to, the boat ramp and boat ramp parking lot, dam crest, Lakeview and Rancho Laguna Seca trails, and on-water users (e.g., boaters). Future reservoir levels would be higher than~~l~~ levels under the Pre-FERC Order Conditions Baseline, as shown in Photos 5 through 7 and 10 in **Figure 3.1-3** ~~**Figure 3.1-2**~~.

In addition, as noted in Chapter 2 *Project Description*, operational activities would involve providing winter base flows, pulse flows, and summer flows to support multiple life stages of steelhead trout and salmon. These operational flow releases would support and maintain riparian vegetation growth and thus have a beneficial effect on multiple public vantage points looking toward Coyote Creek, including the Live Oak Picnic Area and Coyote Creek Trail, and would improve the Project Area’s visual character relative to the existing conditions baseline. As described in Chapter 3 *Introduction*, historical water releases were made year-round, but were generally higher in the summer months. Compared to Pre-FERC Order Conditions Baseline, operational Project flow releases would also support and maintain riparian vegetation growth. This increase in operational flows would have a beneficial effect on views from multiple public vantage points looking toward Coyote Creek and would have a similar visual character relative to Pre-FERC Order Conditions Baseline of the Project Area. Because post-construction Anderson Dam facilities operations would not degrade visual character or quality of public views, the impact would be less than significant.

Conservation Measure Operations

Ogier Ponds CM

Similar to conditions under the existing conditions baseline found throughout Coyote Creek, water levels in the creek and Ponds ~~1,~~ 2, 3, and 4 ~~5~~ would fluctuate and vary on a seasonal basis. Operations and maintenance activities for the Ogier Ponds CM would include vegetation management, routine inspections and repairs to the berms, access roads, spillways, fish screens, habitat enhancements, rock slope protection, and trash and graffiti removal. These operations and maintenance activities are not expected to result in visual impacts, as these activities would be temporary and conducted within a short timeframe. these reasons, operations and maintenance of the Ogier Ponds CM would not substantially degrade the visual character or quality of public views of this area. Impacts would be less than significant.

Phase 2 Coyote Percolation Dam CM

Maintenance activities for the Phase 2 Coyote Percolation Dam would include periodic sediment removal, vegetation management, rock slope protection, and routine inspection and repairs to the roughened channel and habitat enhancements. Operational activities associated with the Coyote Percolation Dam would include raising, lowering, and deflating the dam during specific flow events (as described in Chapter 2 *Project Description*). These operational activities would be consistent with existing operations with Coyote Percolation Dam. Operations and maintenance activities for the Phase 2 Coyote Percolation Dam CM would not result in a substantial visual change, because these activities would be temporary within a short timeframe. Therefore, operation and maintenance would not substantially degrade the visual character or quality of public views of this area. Impacts would be less than significant.

North Channel Reach ~~Extension~~

Maintenance ~~and operations~~ of the ~~activities for the~~ North Channel Reach ~~Extension CM~~ would include routine monitoring and inspection, and clearing the channel of debris or repairing the wetland bench, if necessary ~~vegetation management, and regrading and dewatering activities if needed~~. These ~~operations and~~ maintenance activities are covered in the SMP, and impacts would be similar to those disclosed in the in the SMP EIR. Impacts associated with the North Channel Reach ~~Extension operations and~~ maintenance would not substantially degrade the visual character or quality of public views of this area. Therefore, impacts related to maintenance ~~and operations~~ of the North Channel Reach ~~Extension~~ would be less than significant.

Spawning Gravel and Rearing Habitat Improvements

Maintenance Activities at the Live Oak Restoration Reach and implementation of the Sediment Augmentation Program along Coyote Creek may require short-term closures of the Coyote Creek Trail, limiting views of those work areas. The visual disruptions to recreators would be temporary and short in duration and limited to the period of placement of sediments. Depending on the public visibility of the specific sites, maintenance of rearing habitat improvements would incrementally improve viewing conditions or would not result in a substantial visual change as natural habitats along the creek corridor are restored. For these reasons, Maintenance Activities at the Live Oak Restoration Reach would have a less-than-significant impact on public views and the visual character and quality of the sites and surrounding areas.

Post-Construction Project and FAHCE Adaptive Management

The implementation of adaptive management actions as part of the Project and FAHCE Adaptive Management Program may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek watershed, such as exotic species removal, replacement riparian plantings, or additional sediment augmentation. These actions would occur when Dam flow releases or Conservation Measures are not functioning as intended, or not meeting Project or FAHCE measurable objectives. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. Implementation of Valley Water BMPs and VHP Conditions, and AMMs, as described for Seismic Retrofit components above, would reduce the effects on the visual character and quality of views from the Coyote Creek Trail and other publicly accessible trails in Coyote Creek Parkway. Adaptive actions would be minor in nature and, in some cases, improve visual conditions through removal of exotics species and installation of replacement plantings. Because post-construction Project and FAHCE AMP actions would not substantially degrade the visual character or quality of public views, impacts would be less than significant.

Significance Conclusion Summary

During the Project's construction phase, implementation of Valley Water BMPs WQ-11, REVEG-1, REVEG-2, BI-8, and VHP Condition 7, and AMMs Aquatic 40, Aquatic 71, and Aquatic 103 would require that work areas are kept clean, disturbed areas are reseeded, ecologically appropriate seed mixes are applied to revegetated areas to help improve visual conditions post-construction, and mature vegetation is replanted with native species. Given the high visibility of Staging Areas 1 and 4 from Cochrane Road and the visibility of Staging Area 1 and the BHBA post-construction from the Rosendin Park area, the Project's construction impacts would be significant. **Mitigation Measure AES-1** would require replacement of mature, healthy native trees that are removed along Coyote Creek at the Live Oak Picnic Area, BHBA, and other County-operated parklands to compensate for the removal of mature, healthy native trees that occurs along this creek corridor. However, because of the long time period until the replanted trees mature, a period of up to 20 years, the impact significance threshold would be exceeded, and this impact would be **significant and unavoidable**.

Motorist and pedestrian views of Staging Areas 1 and 4 would be accessible from Cochrane Road during Project construction. Implementation of **Mitigation Measure AES-2** would screen portions of these areas from pedestrians and motorists using Cochrane Road; because the existing visual character or quality of public views of the staging areas would not be substantially degraded and the impact significance threshold would not be exceeded, this impact would be **less than significant with mitigation**.

Limited tree and vegetation removal may also be necessary for select Conservation Measures, including, but not limited to, the Ogier Ponds CM~~,~~ and the Phase 2 Coyote Percolation Dam CM~~,~~ ~~and North Channel Extension~~. Only the Ogier Ponds CM ~~and North Channel Extension~~ would include substantial removal of mature, healthy native trees. This tree removal would degrade the visual resources at these sites, and the impact would be significant. Implementation of

Mitigation Measure AES-1 would require native trees to be planted in areas where removal of mature, healthy native trees has occurred and caused significant impacts on scenic resources. **Mitigation Measure AES-1** would also require replacement of mature, healthy trees that are removed from County-owned parklands at the Ogier Ponds ~~and the North Channel Extension~~ work area to compensate for the removal of mature, healthy native trees. Implementation of this mitigation measure would reduce adverse impacts on scenic resources. However, because of the long period that it takes for young oak trees to grow to a size similar to the size of trees to be removed, even after implementation of this mitigation measure, the impact at these sites would be **significant and unavoidable**.

As described above, post-construction operation of the Seismic Retrofit components and Conservation Measure components would have a less-than-significant impact on the visual character and quality of public views of affected areas. In addition, operating the reservoir at full capacity would improve overall visual conditions of the reservoir, compared to the existing conditions baseline, as higher water levels and open water have high aesthetic value. This impact would be **less than significant**.

Lastly, since adaptive actions implemented as part of the FAHCE AMP would be minor in nature and may improve the aesthetics due to exotic removal activities and installation of replacement plantings, these actions would have a **less-than-significant impact** on visual character and visual quality of public views.

Mitigation Measures

AES-1 Replacement Trees on Santa Clara County Parkland

Consistent with the approach in section C16-7 of the County's Tree Preservation and Removal Ordinance, Valley Water will prepare a replanting and/or re-vegetation plan for all County ordinance-sized trees to be removed on County-owned parkland. Replacement trees will be of a like kind and species of tree removed, if native and feasible, or of a kind and species to be determined by Valley Water in coordination with the County. The replacement trees will be replaced in same location of the tree removed, unless otherwise specified by the County Department of Parks and Recreation. Replacement tree planting size and ratio will be as follows, unless the County Department of Parks and Recreation requests a lower replacement ratio:

- For the removal of each small tree (12 to 18 inches): two 24-inch boxed trees or three 15-gallon trees
- For the removal of each medium tree (18 to 24 inches): three 24-inch boxed trees or four 15-gallon trees
- For the removal of each tree larger than 24 inches: four 24-inch boxed trees or five 15-gallon trees

AES-2 Visual Screening of Construction Staging Areas

Throughout the construction period, Valley Water will require contractor(s) to install and maintain visual screening around portions of construction Staging Areas 1 and 4 that would be publicly visible to nearby pedestrians and motorists. Specifically, contractor(s) will install visual screening along the southern perimeter of Staging Area 1 and southwestern perimeter of Staging Area 4, which abut Cochrane Road. Visual screening materials typically used on construction sites may include chain-link fencing with privacy slats, fencing with windscreen material, or wood or other similar barriers, approximately 6 to 8 feet tall, comprised of natural colors (e.g., green, brown, tan) found in the surrounding area.

Impact AES-3: Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area (Less than Significant with Mitigation)

Seismic Retrofit Construction

As described in Chapter 2, *Project Description,* Seismic Retrofit construction activities would routinely occur during daytime hours between 6:00 a.m. and 6:00 ~~4:00~~ p.m. During the daytime hours, the sun's reflection on equipment may create a new source of glare. However, due to the combination of distance from work areas and the nearest sensitive viewers and intervening topography, daytime construction activities would not create a substantial source of light or glare.

Earthwork resulting from the excavation of the existing dam and construction of the replacement dam and spillway, conversion of the Stage 1 Diversion System to the Stage 2 Diversion System, tunneling for the HLOW and LLOW, communications/paving activities on Cochrane Road and support production (e.g., concrete placement) would require work during early mornings, evening, and nighttime hours, and therefore, construction lighting would be necessary during these times. Given delivery vehicles could occur on the Project site until 8:00 p.m., these vehicles may introduce light after sunset during winter, but this effect is minor since they are present only briefly along public roadways. The work requiring construction lighting is anticipated to occur throughout Seismic Retrofit construction, including on Saturdays and select Sundays, as necessary. Additionally, in the event of an emergency, some additional nighttime work and associated lighting may be needed. Due to distance, topography and/or intervening vegetation, most nighttime, evening, and early morning construction activities would not be visible from nearby public roads or vantage points. However, depending on where nighttime, evening, and morning activities occur, limited construction lighting may be temporarily visible from nearby public roads, which would be a substantial new source of substantial nighttime lighting adversely affecting public views. This would be a significant impact.

Implementation of **Mitigation Measure AES-3** and VHP Condition 7 would reduce adverse effects on nighttime, evening, and morning views due to construction lighting to a level that is less than significant with mitigation.

Conservation Measure Construction

Construction activities associated with the Conservation Measures, other than the Ogier Ponds CM, would largely occur during daytime hours, while the sun's reflection could generate glare. These activities would largely occur in areas where the construction activities are at least partially screened from public view points by mature vegetation, or are located in areas that are obscured by the natural topography and distance from large numbers of sensitive viewers. For these reasons, construction of the Conservation Measures would not introduce a new substantial source of light or glare that would adversely affect day or nighttime views of the Conservation Measures work areas.

Throughout the construction of the Ogier Ponds CM, similar to the other Conservation Measures, any light or glare coming from the work area would be largely obscured due to mature vegetation that is present surrounding and within the work area, the natural topography of the site, and/or the distance of the work area to public vantage points. However, trucks would be required to deliver materials to the work area to support pond filling activities 24 hours a day. This would result in the addition of light sources on access roads from delivery trucks and work area lighting in the staging area where materials would be deposited and stored. This additional source of light in the existing setting would be considered a nuisance, as currently access roads and Project area do not support substantial sources of lights. Therefore, through creating a substantial new source of nighttime lighting adversely affecting public views, the delivery of project materials throughout the nighttime hours would result in a significant impact. Implementation of **Mitigation Measure AES-3** and VHP Condition 7 would reduce adverse effects on nighttime views due to truck lighting to a level that is less than significant with mitigation.

Post-Construction Anderson Dam Facilities Operations

Following construction of Seismic Retrofit components, existing lighting (e.g., lighting at the Anderson Dam boat ramp parking lot) would be replaced with new permanent lighting. This lighting would not differ substantially from current lighting systems and lighting systems used in the past throughout the study area. Therefore, operation of the Project would not create a new source of substantial light or glare that would adversely affect day or nighttime views of the Project Area. Therefore, impacts would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

As noted above, implementation of adaptive management actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek watershed such as exotic species removal, replacement riparian planting, or additional sediment augmentation. These activities would occur during daytime hours. The sun's reflection could generate a source of glare from construction equipment; however, work activities would be largely screened by mature vegetation and/or away from large numbers of sensitive viewers, and work would be relatively limited in scale. As such, adaptive management actions, as part of the FAHCE AMP, would not introduce a new substantial source of light or glare that would adversely affect day or nighttime views in the Coyote Creek watershed. Therefore, this impact would be less than significant.

Significance Conclusion Summary

Use of lighting during early morning, evening, and nighttime construction activities, materials delivery, and emergency activities may create a new source of substantial light adversely affecting nighttime views of nearby motorists traveling on public roads near the Seismic Retrofit and Ogier Ponds CM construction areas. Views of such lighting would be a significant impact; however, **Mitigation Measure AES-3** and VHP Condition 7 would require that lighting from the construction areas is shielded, directed downwards and/or away from public roadways and motorists. With this measure implemented, substantial new sources of light and glare would not adversely affect nighttime views of construction areas, and this impact would be **less than significant with mitigation.**

Once construction of Seismic Retrofit components are completed, existing lighting would be replaced with permanent lighting, as needed (e.g., at the Anderson Dam boat ramp parking area, safety lighting). Replacement lighting would not be substantially different from current lighting throughout the Project Area. Therefore, this impact would be **less than significant.**

With respect to construction of Conservation Measures, outside of the Ogier Ponds CM, work activities would be small in scale and conducted during the daytime. These activities would mostly be screened by mature vegetation and/or occur away from large numbers of sensitive viewers. These components would not introduce a new substantial source of light or glare, and this impact would be **less than significant.**

Based on the summary above, Project impacts on light and glare would be **less than significant with mitigation.**

Mitigation Measures

AES-3 Construction Lighting

Valley Water will require contractor(s) to shield construction lighting used during nighttime construction to implement construction activities associated with the Seismic Retrofit and Ogier Ponds CM. A *light shield* is a product, generally of metal, that blocks the direction of light. The contractor(s) will determine the precise light shield(s) to be used. Installing light shields will minimize the amount of nuisance light that is visible from public roadways throughout the Project Area <u>and the amount that illuminates sensitive habitats and natural lands outside of the construction area</u>. Direct lighting will also be focused downward or oriented such that the light sources are not directed toward nearby public roadways and motorists<u>, or toward sensitive habitats and natural lands outside of the construction area.</u> This will be accomplished through the use of lighting fixtures that are manufactured to limit the candle width for which light is generated from each fixture. The addition of screens (e.g., fencing, vegetation, boards) will also be used if light is highly visible from public roadways, as determined by Valley Water. Additional barriers (i.e., fencing) will also be constructed along access roads that would be used for 24-hour delivery of project materials, such as those required for the construction of the Ogier Ponds CM. The height and materials used for these barriers will be determined by the contractor and approved by Valley Water, depending on the location, light source, and timeline that the barriers will be required to minimize light impacts from the site.

3.1.6 Cumulative Aesthetic Impacts

The geographic study area for the cumulative impact analysis for aesthetics encompasses the future Project Areas and local public viewsheds. The primary sources of nighttime lighting and glare in the County are associated with urban areas; within open space areas, nighttime lighting and glare are less pronounced and associated with residential uses.

This section describes the Project's contribution to cumulative aesthetic impacts, as summarized in **Table 3.1-6**.

Cumulative impact thresholds for aesthetics are the same as the impact thresholds presented in Section 3.1, *Aesthetics*.

Table 3.1-6. Summary of Project Impact Contribution to Cumulative Aesthetic Impacts

Impact	Cumulatively Considerable with FOCP?	Cumulatively Considerable with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact AES-1: Substantial damage to scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway	No	No	NCC	N/A	No
Cumulative Impact AES-2: Substantial degradation of the existing visual character or quality of public views of the site and its surroundings	Yes	No	CC	MM AES-1 MM AES-2	Yes
Cumulative Impact AES-3: Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area	No	Yes	CC	MM AES-3	No

Key: CC = cumulatively considerable; FOCP = FERC Order Compliance Project; MM = Mitigation Measure; N/A = not applicable; NCC = not cumulatively considerable

***Cumulative Impact AES-1: Substantial damage to scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway* (Not Cumulatively Considerable)**

As noted in the analysis under Impact AES-1 above, Project impacts to scenic resources within state scenic highway would be less than significant because there are no state scenic highways with the Project's study area. East Dunne Avenue and US 101 are identified by the Santa Clara County and San Jose General Plans, respectively, as local scenic corridors. Construction of the Seismic Retrofit components of the Project would not adversely affect rock outcroppings or historic buildings within a state scenic highway. While tree removal would affect local scenic resources, such as parks, trails, and scenic corridors, by removing a substantial number of mature trees, this impact is addressed in Cumulative Impact AES-2. Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operational timeframes overlap within the same viewsheds of elements of the Project and affect similar scenic resources.

Cumulative Effects of Project with the FOCP

The FOCP will remove trees at the Toyon Group Picnic Area and require some minor vegetation removal as part of the construction of the tunnel outlet at Anderson Dam, bladder dam installation at the Coyote Percolation Pond, and levee and floodwall elements of the Coyote Creek Flood Management Measures; cumulative aesthetics impacts of tree removal impacts are evaluated in Cumulative Impact AES-2. The FOCP would be completed before Project-related construction activities begin. There are no state scenic highways in the Project study area. Therefore, there would be no cumulative effect with regard to the Project with the FOCP.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most of the other reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, would occur outside the viewshed of Project's construction and operational activities (as described in Section 3.1). Certain future projects, such as the SMP and County Parks Planning Projects and Natural Resource Management, could have temporary impacts to scenic resources along Coyote Creek in the same areas as Project activities, but effects from these projects would be minor and conducted with the goal of beneficial effects long-term on scenic resources in the cumulative study area. Other future projects, such as Valley Water's other seismic retrofit, dam improvement, and flood protection projects, as well as development projects in the County, would result in temporary and long-term impacts on scenic resources. Probable future projects would be required to comply with tree preservation policies and other development standards that would reduce their impacts on scenic resources. However, these impacts would not be cumulatively considerable because they would largely occur in different viewsheds. The cumulative impact on scenic resources resulting from the Project in combination with other probable future projects would not be significant and the Project's contribution would not be cumulatively considerable. Cumulative aesthetics impacts of tree removal impacts are evaluated in Cumulative Impact AES-2.

Significance Conclusion Summary

There are no state scenic highways in the Project study area and the impacts attributable to probable future projects would not be cumulatively considerable because they would occur in different viewsheds (i.e., outside the viewshed of Project construction and operational activities). The cumulative impact on scenic resources resulting from the Project in combination with other probable future projects would not be significant, and the project's contribution would **not be cumulatively considerable**. Cumulative aesthetics impacts of tree removal impacts are evaluated in Cumulative Impact AES-2.

Mitigation Measures

No mitigation is required.

Cumulative Impact AES-2: Substantial degradation of the existing visual character or quality of public views of the site and its surroundings **(Cumulatively Considerable)**

In addition to the removal of mature trees, the extent of Project construction activities would encompass a large area over a temporary, but extended period (7 years), temporarily disrupting public views from the Rosendin Park Area and from local roads to the west of the dam, including Cochrane Road. The dewatered reservoir and Stockpile Area K would also be visible from the Holiday Estates neighborhood. Once construction is completed, most Project components would be similar in character to the existing facilities, although the BHBA would permanently appear different as a result of major excavation.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they degrade the visual character of same public views as elements of the Project.

Cumulative Effects of Project with the FOCP

Reservoir drawdown and the lowering of water levels during the FOCP will result in adverse effects to the surrounding viewshed. Specifically, views from nearby residences, the Holiday Lake Estates, and recreationists would be adversely affected. Trails within the Rosendin Park Area, located southeast of the Project site and ~~would remain open,~~ including the Lakeview ~~Lake View~~, Gray Pine, Rosendin, Cochrane, and Rancho Laguna Seca trails, would remain open except for blasting activities during Years 4, 5, and/or 6. In addition, the visual character in and around the reservoir would be impacted by staging areas and construction activities from both projects. Because of the duration of time the reservoir would be maintained at deadpool and subject to construction activities (e.g., through both the FOCP and the Project), adverse effects on the visual character will be a significant cumulative impact, and the Project's contribution would be cumulatively considerable.

The FOCP would also remove trees at the Toyon Group Picnic Area and require retaining walls and buttressing of potential landslide areas on the south arm of the reservoir. Although the FOCP would be completed before Project-related construction activities begin, the Bank and Rim Stability Improvements along the reservoir and tree removal at the Toyon Group Picnic Area for construction staging would not be fully restored, such that the additional loss of tress around the Anderson Lake County Park from the Project in addition to permanent changes to the BHBA would result in significant cumulative effects to the visual character around Anderson Reservoir, and the Project's contribution would be cumulatively considerable.

Other elements of the FOCP are at discrete and separate locations and/or time from Project activities that would not create a cumulative effect on visual character.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most of the other reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, would occur outside the viewshed of Project's Seismic Retrofit construction. Certain future projects, such as the Santa Clara Valley Habitat Restoration Program and County Parks Planning Projects and Natural Resource Management, are focused on long-term restoration of existing open space areas, leading to improvement of visual character and quality of public views in the Project Area. Other future projects, such as Valley Water's other seismic retrofit, dam improvement, and flood protection projects, as well as development projects in the County, would result in temporary and long-term impacts on visual character, particularly to construction-related tree removal. Probable future projects would be required to comply with tree preservation policies and other development standards that would reduce their impacts on visual resources. However, these impacts would not be cumulatively considerable, because they would occur in different viewsheds. The cumulative impact on visual character resulting from the Project in combination with other probable future projects would not be significant, and the Project's contribution would not be cumulatively considerable.

Significance Conclusion Summary

Valley Water would reduce the Project's proportion of impacts on visual character and public views through implementation of BMP WQ-11 would require that work areas are kept tidy and clean to the extent possible; BMP BI-8 would help ensure that an ecologically appropriate seed mix is applied to revegetated areas. **Mitigation Measure AES-2** requires that portions of these staging areas must be screened from views by pedestrians and motorists using Cochrane Road. These measures would reduce the severity of the impact to visual character as observed from Cochrane Road from an extended construction period and drawdown of water levels at Anderson Reservoir. However, Project activities at the BHBA would have a permanent change on public views accessible from the Rosendin Park Area. Therefore~~, but~~ the cumulative impact would ~~still~~ be significant, and the Project's contribution is **cumulatively considerable.**

Valley Water would reduce the Project's incremental contribution to cumulative impacts on the loss of mature trees in the park through implementation of BMPs REVEG-1 (Seeding), REVEG-2 (Planting Material), and BI-8 (Choose Local Ecotypes of Native Plants and Appropriate Erosion-Control Seed Mixes), which would incorporate ecologically appropriate plants at restored work areas following construction of proposed Conservation Measures. However, because users of the Anderson Lake County Park have higher expectation of scenic views, removal of mature trees along the Coyote Creek riparian corridor within the Live Oak Picnic Group Area would be a significant and cumulatively considerable impact before mitigation. **Mitigation Measure AES-1** requires replanting trees where mature trees greater than 18 inches in diameter at breast height would be removed. Implementation of this mitigation measure would reduce the severity of the impact but given the time that would be necessary for replacement trees to grow to maturity, the Project's contribution to cumulative impacts on visual character is still **cumulatively considerable**.

Mitigation Measures

AES-1 Replacement Trees on Santa Clara County Parkland

AES-2 Visual Screening of Construction Staging Areas

Cumulative Impact AES-3: Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area **(Not Cumulatively Considerable)**

Project construction activities would occur primarily during daytime hours; however, earthwork on the excavation of the existing dam and construction of the replacement dam and spillway, conversion of the Stage 1 Diversion System to the Stage 2 Diversion System, tunneling for the HLOW and LLOW, communications/paving activities on Cochrane Road and support production (e.g., concrete placement) would require work during early morning, evening, and nighttime hours. Therefore, early morning, evening, and nighttime construction lighting would be necessary during these work phases.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they create light or glare in the same Project Area and at the same time as the Project.

Cumulative Effects of Project with the FOCP

The FOCP would be completed before construction activities for the Project begin; these two projects would not result in cumulative impacts related to light and glare. There would be no cumulative effect.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Many of the other reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, when combined with impacts of the Project (as described in Section 3.1), could result in new sources of substantial light and glare. Construction activities related to Valley Water's other seismic retrofit, dam improvement, and flood protection projects, for example, would result in similar impacts in the event of nighttime work, as would other development projects in the County. Although the other probable future projects would be required to comply with lighting requirements and other development standards, during both construction and operation/maintenance, that would reduce their lighting impacts, the cumulative impact related to light and glare resulting from the Project in combination with these other probable future projects would be significant.

Significance Conclusion Summary

Project construction activities would routinely occur during daytime hours; however, earthwork on the excavation of the existing dam and construction of the replacement dam and spillway, conversion of the Stage 1 Diversion System to the Stage 2 Diversion System, tunneling for the HLOW and LLOW, communications/paving activities on Cochrane Road and support production (e.g., concrete placement) would require work during early morning, evening, and nighttime hours. Therefore, early morning, evening, and nighttime construction lighting would be necessary during these work phases. Additionally, in the event of an emergency, some nighttime work and associated lighting may be needed. Due to distance, topography, location in other viewsheds, and/or intervening vegetation, it is anticipated that most early morning, evening, and nighttime construction activities would not be visible from nearby public roads or residences. However, depending on where these activities occur, early morning, evening, and nighttime construction lighting could be temporarily visible from nearby residences and public roads, which could be a nuisance to nearby residents and motorists traveling on local roads. This is a significant cumulative impact when added to the impacts of other probable future projects, and the Project's contribution would be cumulatively considerable. **Mitigation Measure AES-3** requires that lighting is shielded and directed downward and/or away from residential areas. Through implementation of **Mitigation Measure AES-3**, the Project's contribution to cumulative impacts related to light and glare would be **not cumulatively considerable**.

Mitigation Measures

AES-3 Construction Lighting

3.2 Agriculture and Forestry Resources

This section evaluates the Project's impacts on the study area that has been defined for agricultural resources. The CEQA guidelines significance criteria for agricultural resources address impacts related to conflicts with Williamson Act contracts or existing zoning for agricultural use and the conversion of agricultural land to nonagricultural uses.

The study area used to assess impacts to agricultural resources consists of all active and inactive agricultural lands and farmlands within a 1-mile radius of the Project area; this includes the construction limits of the Seismic Retrofit and Conservation Measure components (**Figure 2-3** in Chapter 2, *Project Description*) that are located within the County, San José, or Morgan Hill. Several of these areas are identified as Prime and Non-Prime Farmland, or are lands under Williamson Act contracts. Existing conditions for the agricultural setting, including agricultural designations and zoning for these areas, are described below.

Note that no designated forest lands would be affected by the Project as there are no designated forest lands or lands used for commercial timber production in the Project Area. Therefore, forestry resources are not addressed in this section.

3.2.1 Environmental Setting

3.2.1.1 Local Agricultural Context

From the mid-1900s to the present day, the County has been actively transitioning from an agricultural area to a significantly urbanized region, driven by the growth of the technology industry (County 1994). Today, most of the agricultural land and farmlands in the northern end of the Santa Clara Valley have already been converted from agricultural to urban uses. However, the southern end of the valley (including Morgan Hill, part of which is within the study area) has an active agricultural industry.

3.2.1.2 Santa Clara County

According to the California Department of Conservation's (CDOC's) Farmland Mapping and Monitoring Program (FMMP), agricultural lands (farmland and grazing land) accounted for 50 percent of the total land area in the County in 2018 (CDOC 2021a ~~2021d~~). Based on statistics for 2020, the gross agricultural production value of the County was over $321 million (County Department of Agriculture 2022).

When the County's General Plan was prepared in 1994, the County had approximately 457,000 acres of agricultural land, of which most (approximately 405,000 acres) was rangeland (County 1994). As of 2018, the County had 14,370 acres of Prime Farmland, 3,293 acres of Farmland of Statewide Importance, and 2,236 acres of Unique Farmland, most of which is located in the southern portion of the County (CDOC 2021a ~~2021d~~).

3.2.1.3 City of Morgan Hill

The southern portion of the study area is located within Morgan Hill. Agriculture has been important to Morgan Hill as an industry and employment generator throughout the City's history and has contributed to its rural character. The City of Morgan Hill 2035 General Plan

Draft EIR identifies a total of 7,686 acres of agricultural land within the Morgan Hill Sphere of Influence (SOI) (City of Morgan Hill 2014), most of which is grazing land. Prime Farmland is largely located east of US 101, in the southern portion of the City. **Table 3.2-1** lists the acreage of each Important Farmland category within the Morgan Hill SOI (City of Morgan Hill 2014).

Table 3.2-1. Agricultural Acreage within Morgan Hill SOI

Farmland Classification	Within City Limits (acres)	Total Area (acres)
Prime Farmland	315	1,386
Farmland of Statewide Importance	22	196
Farmland of Local Importance	153	346
Unique Farmland	30	234
Grazing Land	1,265	7,686
Total	1,785	9,848

Source: City of Morgan Hill 2014, based on Farmland Mapping and Monitoring Program GIS data, 2012.

The City of Morgan Hill has active Williamson Act contracts on both Prime and Non-Prime Farmland (**Table 3.2-1**) (City of Morgan Hill 2014). In 2015, 1,703 acres of land were under ongoing Williamson Act contracts within city limits, with 765 acres in non-renewal. Of the lands under Williamson Act contracts, 586 acres were designated as Prime Farmland, Farmland of Statewide Importance, Farmland of Local Importance, Unique Farmland, or Grazing Land by the FMMP.

3.2.1.4 City of San José

The northwest portion of the Project Area is located within San José. The Envision San José 2040 General Plan (City of San José 2023a ~~2012~~) addresses agricultural land use designations within the City; generally, the City of San José and County share the goal of maintaining non-urban land uses. Currently, the portion of the Project Area that is located within San José is zoned in residential districts (see **Figure 3.15-1** in section 3.15, *Land Use and Planning*) (City of San José 2021a, 2023b ~~2021b~~), and is not considered agricultural land or farmland. Furthermore, the land is not designated as Important Farmland but rather Urban and Built-up Land and Grazing Land (County 2021). Therefore, San José's agricultural land use is not discussed further in the EIR.

3.2.1.5 Agricultural Resources in the Project Area

CDOC Farmland Designations

CDOC's Important Farmland Finder shows that the Project Area does not contain any lands designated as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (**Table 3.2-2**) (County 2021). The agricultural land use designations within the Project Area contains primarily Grazing Land (88 acres) and Urban and Built-up Land (27.5 acres). **Table 3.2-3** indicates that Grazing Land (6,290.5 acres) and Urban and Built-up Land (1,491.3 acres) are also the predominant agricultural land use designations within a 1-mile radius of the Project Area.

Figure 3.2-1a-c shows Important Farmland designations and other agricultural land designations within a 1-mile radius of the study area. One parcel west of the study area, located along

Cochrane Road near the base of the dam, contains Farmland of Local Potential, as defined above (County 2021). Several parcels southwest of Ogier Ponds area are designated as Prime Farmland or Farmland of Statewide Importance, and parcels designated as Farmland of Local Potential are located east of Ogier Ponds, adjacent to US 101.

Most of the land within the study area and within a 1-mile radius is classified as Non-Williamson Act Urban and Built-Up Land, with a few parcels enrolled as Williamson Act Non-Prime Agricultural Land. This includes several parcels with active or non-renewed Williamson Act contracts west of the Ogier Ponds that are outside of the Project Area but within a 1-mile radius. Williamson Act Non-Prime Agricultural Land is enrolled under the California Land Conservation Act contract and does not meet any of the criteria for classification as Prime Agricultural Land but is rather defined as Open Space Land of Statewide Significance (County 2021).

Table 3.2-2. Agricultural Land Designations within the Project Area

Designation	Total Area (acres)	Percent of Project Area
Prime Farmland	0	0
Farmland of Statewide Importance	0	0
Unique Farmland	0	0
Grazing Land	88.0	15
Farmland of Local Importance	0.4	~0
Farmland of Local Potential	16.9	3
Other Land	1.2	~0
Urban and Built-up	27.5	5
Water	433.8	76
Total	567.8	100

Source: Santa Clara County 2021

Table 3.2-3. Agricultural Land Designations within a 1 Mile Radius of the Project Area

Designation	Total Area (acres)	Percent of Area within 1 Mile
Prime Farmland	169.2	2
Farmland of Statewide Importance	4.2	~0
Unique Farmland	39.3	~0
Grazing Land	6,390.5	62
Farmland of Local Importance	397.6	4
Farmland of Local Potential	87.3	1
Other Land	574.6	6
Urban and Built-up	1,491.3	14
Water	1,145.5	11
Total	10,299.5	100

Source: Santa Clara County 2021

Agricultural Land Use and Zoning Designations

Land uses in the Project Area include parcels classified as grazing lands, single-family rural residences, and parklands on privately owned, Valley Water-owned, and County-owned property. The Project Area does not include land currently in active grazing or large-scale agricultural production. Most of the study area is located within the jurisdiction of the County or the City of San José, with a small portion located within the City of Morgan Hill. General plan land use and zoning designations within each jurisdiction are described in detail in section 3.15, *Land Use and Planning* and shown in **Figure 3.15-1**; the information is summarized here as applicable to evaluating the Project impacts on agricultural resources.

There are three parcels within the Seismic Retrofit component Project Area that are zoned for agricultural use. One privately owned property on Cochrane Road (APN 728-34-010) supports small-scale agricultural activity. The other privately owned property along Cochrane Road (APN 728-34-011) is zoned for agricultural use, but there currently are no agricultural activities on the property. A third parcel in the Project Area (APN 728-34-018), located immediately downstream of the dam, is zoned for agricultural use but the existing land use is open space/utility; the property contains outlet works and an undeveloped portion of Coyote Creek. In addition, the Ogier Ponds CM area is currently zoned for exclusive agriculture, although the site is currently occupied by seasonal wetland ponds and used for recreational purposes.

3.2.2 Regulatory Setting

This section summarizes laws, regulations, policies, and plans pertinent to the evaluation of the Project's impacts on agricultural resources. No specific federal laws, regulations, or policies related to agricultural resources are applicable to the Project.

3.2.2.1 State Laws, Regulations, and Policies

Farmland Mapping and Monitoring Program

The CDOC established the FMMP to document changes in agricultural land use since 1984. The non-regulatory program provides a consistent and impartial analysis of agricultural land use and land use changes throughout California. Agricultural land is rated according to soil quality and irrigation status and is described in different categories below. The maps are updated every 2 years with the use of a computer mapping system, aerial imagery, public review, and field reconnaissance. The FMMP defines Important Farmland in the following categories (CDOC 2021b ~~2021a~~):

> **Prime Farmland:** Prime Farmland is land that has the best combination of physical and chemical characteristics for the long-term production of crops. It has the soil quality, growing season, and moisture supply needed to produce sustainable high yields of crops when treated and managed, according to current farming methods. Prime Farmland must have been used for the production of irrigated crops at one point in time during the 4 years prior to the mapping date.

> **Farmland of Statewide Importance:** Farmland of Statewide Importance is land other than Prime Farmland that has a good combination of physical and chemical characteristics for the production of crops but has minor shortcomings, such as greater slope or less ability to store

soil moisture. It must have been used for the production of irrigated crops at one point in time during the 4 years prior to the mapping date.

Unique Farmland: Unique Farmland is land of lesser quality soils that has been used for the production of the state's leading agricultural crops at one point in time during the 4 years prior to the mapping date. This land is usually irrigated but may include non-irrigated orchards or vineyards as found in some climatic zones in California. Examples of such crops may include oranges, olives, avocados, rice, grapes, and cut flowers.

Farmland of Local Importance: Farmland of Local Importance is land of importance to the local agricultural economy as determined by each county's board of supervisors and a local advisory committee. In some counties, confined animal agriculture facilities are part of Farmland of Local Importance, but they are shown separately.

Farmland of Local Potential: In a few counties, including the County, the local advisory committee has elected to additionally define areas of Farmland of Local Potential. The County defines Farmland of Local Potential to be all lands having Prime and Statewide soil mapping units that are not irrigated, regardless of cropping history or irrigation water availability (CDOC 2018). For reporting purposes, Farmland of Local Potential and Farmland of Local Importance are combined in the FMMP acreage tables but are shown separately on the Important Farmland Map.

California Land Conservation Act of 1965 (Williamson Act)

The California Land Conservation Act of 1965—commonly referred to as the Williamson Act—enables local governments to enter into contracts with private landowners for the purpose of restricting specific parcels of land to agricultural or related open space use (CDOC 2021c~~b~~). In return, landowners receive property tax assessments that are much lower than normal, because they are based on farming and open space uses as opposed to full market value. The Open Space Subvention Act of 1971 provides for the partial replacement of local property tax revenue foregone as a result of participation in the Williamson Act and other enforceable open space restriction programs (CDOC 2021d ~~2021c~~). Lands under the jurisdiction of the Williamson Act are tracked by the County (County 2021).

3.2.2.2 Regional and Local Laws, Regulations, and Policies

Santa Clara County General Plan

The Santa Clara County General Plan sets forth the following goals and policies relevant to agricultural resources in the Project study area (County 1994):

Policy R-RC 57: Agriculture shall be encouraged and prime agricultural lands retained for their value to the overall economy and quality of life of the County, including:

a. local food production capability;

b. productive use of lands not intended or suitable for urban development; and

c. preservation of a diminishing natural resource, prime agricultural soils.

Policy C-RC 37: Agriculture should be encouraged and agricultural lands retained for their vital contributions to the overall economy, quality of life, and for their functional importance to the County, in particular:

a. local food production capability;

b. productive use land not intended for urban development; and

c. protection of public health and safety.

Morgan Hill 2035 General Plan

The Natural Resources and Environment Element of the Morgan Hill 2035 General Plan sets forth the following goals and policies relevant to agricultural resources in the study area (City of Morgan Hill 2017 ~~2016~~).

Goal NRE-4: A viable agricultural industry.

Policy NRE-4.1: Agriculture Retention and Transition to Urban Uses. Support programs and techniques, including conservation easements and purchase of development rights to encourage the retention of agricultural activities and to minimize conflicts in the transition from agriculture to urban uses.

Policy NRE-4.11: Agricultural Mitigation. Enforce the agricultural mitigation requirement of requiring the preservation of a minimum of 1 acre of agricultural land for each acre of agricultural land changed to a nonagricultural use, consistent with the City's Agricultural Lands Preservation Program.

Policy NRE-4.12: Permanent Preservation of Agriculture. Establish areas for the permanent preservation of agricultural lands and programs to accomplish that objective, such as exclusive agricultural zoning, transfer of development rights (TDR) programs, and right-to-farm legislation. (South County Joint Area Plan 14.03)

Policy NRE-4.16: Prioritization of Agricultural Land. Prioritize protection of existing agriculture lands in the Sphere of Influence, outside the Urban Growth Boundary.

Morgan Hill Agricultural Lands Preservation Program

In 2014, the City of Morgan Hill established an Agricultural Lands Preservation Program (City of Morgan Hill 2014) to promote continued and viable agricultural activities in and around Morgan Hill. The program established land use policies and an implementation program to preserve agricultural lands within the Morgan Hill SOI to protect an adequate agricultural land use supply and promote continued and viable agricultural activities in and around Morgan Hill. The agricultural preservation program focuses on the use of agricultural land use easements and in-lieu fees supported by agricultural preservation land use policies.

In particular, the program established an Agricultural Priority Area in the City's Southeast Quadrant as the first priority for acquiring agricultural land conservation easements (**Figure 3.2-1**a-c). This area was selected, because it is the area within the Morgan Hill SOI where agriculture is considered to be the most viable over the long term. Staging Area 5 would be located within this Agricultural Priority Area.

All new private and public development projects under the jurisdiction of the City of Morgan Hill that would directly result in the conversion of agricultural lands are required to mitigate for the loss of agricultural land under the preservation program.

City of Morgan Hill Agricultural Mitigation Ordinance

The City of Morgan Hill adopted an Agricultural Mitigation Ordinance (Ordinance ZA-14-11) in 2015 that established several mechanisms for funding agricultural mitigation.

Anderson Dam Seismic Retrofit Project Environmental Impact Report

1

Envision San José 2040 General Plan

The Envision San José 2040 General Plan sets forth the following policy relevant to agricultural resources in the Project study area (City of San José 2023a ~~2011~~).

> **Policy LU-20.1:** Protect and preserve the remaining farmlands within San José's sphere of influence that are not planned for urbanization in the timeframe of the Envision San José 2040 General Plan, such as mid- and south Coyote Valley, through the following means:
>
> 1. Strongly discourage conversion of agricultural lands outside the Urban Growth Boundary to nonagricultural uses.
> 2. Limit residential uses in agricultural areas to those which are incidental to agriculture.
> 3. Prohibit subdivision of agricultural lands, unless it can be established that the subdivision would not reduce the overall agricultural productivity of the land and that viable agricultural operations would be sustained.
> 4. Encourage contractual protection for agricultural lands, such as Williamson Act contracts, agricultural conservation easements, transfers of development rights, or other property tax relief measures as incentives for preservation of these lands.
> 5. Restrict land uses within and adjacent to agricultural lands that would compromise the agricultural viability of these lands. Require new adjacent land uses to mitigate any impacts on the use of agricultural lands.
> 6. Require ancillary nonagricultural land uses on agricultural lands to be ancillary to and compatible with agricultural land uses, agricultural production, and the rural character of the area, and to enhance the economic viability of agricultural operations.

3.2.3 Methodology and Approach to Impact Analysis

This impact analysis considers whether construction and operation of the Project would result in significant adverse impacts to the environment related to agricultural resources. This analysis focuses on a review of data that has been collected of the study area from relevant general plans, existing farmland mapping of the study area from the CDOC (**Figure 3.2-1**), and results of the desktop evaluations performed using a GIS analysis of this information. The analysis considers temporary impacts, or short-term impacts, that may occur during the 7-year construction period, and permanent impacts, or impacts considered to be long-term and/or those that would result from ongoing operations, maintenance, or adaptive management activities.

The effects of the study area described and evaluated according to significance criteria from Appendix G of the *CEQA Guidelines*, discussed below.

The assessment of impacts for this section has been divided into construction-related impacts and operations-and-maintenance-related impacts by project component, as identified and described in **Table 2-1** of Chapter 2, *Project Description*. Each project component has been analyzed to determine if construction, operation, maintenance, or adaptive management of that component would impact agricultural resources.

3.2.3.1 Seismic Retrofit Construction

As described in Chapter 3.0, *Introduction to Environmental Analysis,* the baseline for evaluating the Seismic Retrofit components construction effects is the existing conditions baseline. The existing conditions baseline consists of conditions at the time of EIR preparation modified by the FOCP implementation, as FOCP activities did not impact agricultural or farmlands. The existing conditions baseline for the impact analysis assumes implementation of the FOCP, which began in 2020. The location and nature of the Seismic Retrofit construction activities are analyzed by determining the effects to existing agricultural land uses within the Project Area. The potential for the Seismic Retrofit components construction activities to conflict with these agricultural land uses are evaluated below.

3.2.3.2 Conservation Measures Construction

As described in Chapter 3.0, *Introduction to Environmental Analysis*, the baseline for evaluating the Conservation Measure components construction impacts is the existing conditions baseline. The existing conditions baseline consists of conditions at the time of EIR preparation modified by the FOCP implementation, as FOCP activities did not impact agricultural or farmlands. This baseline assumes conditions with the implementation of the FOCP, which began in 2020. Similar to the Seismic Retrofit components construction, the location and nature of the Conservation Measure components construction activities are analyzed to determine the effects of the Project on existing agricultural land uses within the Project Area. The potential for the Conservation Measure component construction activities to conflict with these activities is evaluated below.

Conservation Measures components that have been included in the Project and require construction activities and long-term operations include:

- Ogier Ponds CM
- Maintenance of the North Channel Reach ~~Extension~~
- Maintenance Activities at the Live Oak Restoration Reach
- Sediment Augmentation Program
- Phase 2 Coyote Percolation Dam CM

3.2.3.3 Construction Monitoring

Construction monitoring activities are not considered in the agricultural resources impact analysis, as monitoring would involve data and information collection and assessment and would not result in direct or indirect adverse impacts to agricultural resources. Therefore, construction monitoring is not discussed further in this section.

3.2.3.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

Operations of Anderson Dam following construction of the Seismic Retrofit component would involve implementation of the FAHCE rule curves and pulse flows, which may have the potential to result in impacts to agricultural land uses compared to the existing conditions baseline. As described in 3.0, *Introduction to Environmental Analysis,* the baseline for evaluating post-construction operations related to agricultural resources are the existing conditions at the time of EIR preparation modified by the FOCP implementation, as FOCP activities did not impact agricultural or farmlands. This analysis considers impacts to agricultural land uses that would result from operational changes proposed for nonemergency flow releases, following the completion of the Seismic Retrofit construction, as described in Chapter 2, *Project Description*. This analysis considers impacts to agricultural land uses that would result from operational changes proposed for nonemergency flow releases, following the completion of the Seismic Retrofit construction, as described in Chapter 2, *Project Description*.

Additionally, as described in Chapter 2, *Project Description,* Valley Water would maintain the newly retrofitted Anderson Dam and associated infrastructure per the existing Valley Water DMP. Maintenance of Anderson Dam facilities was previously evaluated in the Final DMP Program EIR prepared in January 2012 (State Clearinghouse [SCH] No. 2011082077, Valley Water 2012) that concluded that the DMP would not impact agricultural resources. Impacts to agricultural resource related to post-construction maintenance activities would not differ from the DMP EIR analysis related to agricultural resources, and no new agricultural impacts would result that were not previously disclosed in the DMP EIR. Therefore, post-construction dam maintenance activities are not discussed further in this section.

3.2.3.5 Post-Construction Conservation Measures Operations and Maintenance

The Conservation Measures component consists of improving fish habitat (e.g., gravel augmentation, and the separation of Coyote Creek from Ogier Ponds), and fish passage enhancement. Operations and maintenance of the Conservation Measure components would occur within reaches of Coyote Creek, which are located outside designated farmlands (see **Figure 3.2-1**). The Conservation Measures component would largely operate passively, without mechanical or human intervention, with the exception of the Coyote Bladder Dam that would be actively inflated and deflated, and have been planned in accordance with Anderson Dam Reservoir flow releases. Additionally, as described in Chapter 2, *Project Description*, Valley Water would maintain Coyote Percolation Dam per Valley Water's existing DMP. Maintenance of Coyote Percolation Dam facilities were previously evaluated in the Final DMP EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). Because there are no designated farmlands within the Project area, impacts to agricultural resources during operations and maintenance activities associated with Post-Construction Conservation Measures Operations and Maintenance would not occur. Therefore, these impacts are not discussed further in this section.

3.2.3.6 Post-Construction Project and FAHCE Adaptive Management

The Project and FAHCE AMP would guide post-construction adaptive management of project flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are not evaluated in the impact analysis because they would not result in impacts to agricultural lands or farmlands.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. Impacts of these adaptive actions are not evaluated in the impact analysis because they would not result in impacts on agricultural lands or farmlands.

3.2.3.7 Applicable Best Management Practices and VHP Conditions

As noted in Chapter 2, *Project Description*, Valley Water would incorporate BMPs and AMMs to avoid and minimize adverse effects on the environment that may result from the Project. AMMs are project-specific measures that have been identified to supplement the standard Valley Water BMPs to minimize impacts from Project construction and implementation. All relevant BMPs and AMMs for the study area included in Appendix A ~~B~~, *Best Management Practices and Santa Clara Valley Habitat Plan Conditions Avoidance and Minimization Measures, and Mitigation Measures ~~Incorporated in the Project~~*. There are no relevant VHP conditions or AMMs that would apply to agricultural resources.

BMPs relevant to agricultural resources include the following:

AQ-1: Use Dust Control Measures – would reduce the potential for construction-related dust to damage or reduce the productivity of agricultural activities nearby.

BI-11: Minimize Predator-Attraction – would reduce the potential for pests to be attracted to the Project Area, causing damage to agricultural operations.

WQ-4: Limit Impacts from Staging and Stockpiling Materials – would reduce the potential for equipment at staging areas and stockpiled materials to damage soils in agricultural production.

WQ-11: Maintain Clean Conditions at Work Sites – would reduce the potential for debris to attract pests to the Project Area, causing damage to agricultural operations.

TR-1: Use Suitable Public Safety Measures – would reduce the potential for safety impacts on traffic.

3.2.3.8 Thresholds of Significance

For the purposes of this analysis, the Project would result in a significant impact on agricultural resources if it would:

AG-1: Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to nonagricultural use (criterion a);

AG-2: Conflict with existing zoning for agricultural use or a Williamson Act contract (criterion b).

Issues Dismissed from Further Review

CEQA Guidelines Appendix G also suggests that projects may have a significant effect if they conflict with existing zoning for, or cause rezoning of, forest land (as defined in PRC section 12220[g]), timberland (as defined by PRC section 4526), or timberland zoned Timberland Protection (as defined by Government Code section 51104(g) (criterion c); result in the loss of forest land or conversion of forest land to non-forest use (criterion d); or involve other changes in the existing environment that, due to their location or nature, could result in conversion of Farmland to nonagricultural use or conversion of forest land to non-forest use (criterion e).

The IS circulated with the NOP for the Project dismissed criteria (c) and (d) from further analysis, because no designated forest lands would be affected by the Project. There are no designated forest lands or lands used for commercial timber production in the Project Area. In addition, the IS dismissed criterion (e) from further analysis, because the Project would not involve other changes in the existing environment that could result in the conversion of Farmland to nonagricultural use or conversion of forest land to non-forest use. Therefore, the Project would have no impacts related to these criteria.

During the public scoping period, the public expressed concern about the conversion of Grazing Land and Farmland of Local Potential. These topics are addressed in the analysis of Impact AG-1 below.

3.2.4 Impact Analysis

Impact AG-1: Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland) to non-agricultural use (Less than Significant)

Seismic Retrofit Construction

As depicted in **Figure 3.2-1**, no portion of the Seismic Retrofit Project Area would be located on land designated as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance ("Farmland"). Staging Area 5, however, is located within a Morgan Hill Agricultural Priority Area (defined above), at a site which is not classified as "Farmland." The use of the Morgan Hill Agricultural Priority Area at this location would be temporary, lasting no more than approximately 7 years. This area would also be restored to its pre-existing condition and land use following construction. Based on the preceding analysis, the Seismic Retrofit component would not result in the permanent conversion of Farmland to nonagricultural use.

In addition, BMPs implemented during the Seismic Retrofit components construction would also protect agricultural lands from direct damage or indirect disturbance that could result in conversion or loss of productivity. BMPs AQ-1 (dust control), BI-11 (minimize predator-attraction), and WQ-11 (maintain clean work sites) would require that work sites remain clean and do not attract pests or predators that could alter the agricultural environment. BMP WQ-4 (limit impacts from staging and stockpiling) would minimize impacts on staging and stockpiling areas. BMP TR-1 (public safety measures) would require safety measures to assist agricultural producers and their equipment in avoiding traffic conflicts during construction. These BMPs would minimize the potential for Seismic Retrofit construction to convert Farmland in and within the general vicinity of the Project Area.

Throughout the construction of the Seismic Retrofit component, high flows that may occur within Coyote Creek may flood lands adjacent to the creek, and would have the potential to impact Farmland though the temporary inundation of these lands. Temporary inundation may lead to increased erosion or the destruction of crops within these Farmlands. Because the area of Farmlands located within a mile radius of the Seismic Retrofit component is limited to grazing lands, these impacts would be minimal in nature. Therefore, these impacts would be minimal and short-term in nature, and would not permanently convert Farmland to a non-agricultural use.

Conservation Measure Construction

Construction of most of the Conservation Measures components, including Maintenance of the North Channel Reach ~~Extension~~, Maintenance Activities at Live Oak Restoration Reach, Sediment Augmentation Program, and the Phase 2 Coyote Percolation Dam CM, would not be located on land designated as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance.

Implementation of the Ogier Ponds CM would not require the conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to a non-agricultural land use. It would, however, require the temporary use of 3.8 acres of Farmland of Local Potential (which is not included in the definition of "Farmland") on the southwest side of Coyote Creek near Pond 1 for staging of construction equipment and import materials (see **Figure 3.2-1b**). As noted above, Farmland of Local Potential does not account for whether the land is currently irrigated, the history of cropping on the land, or the feasibility of future irrigation. It is identified by the County due to its agricultural soil mapping characteristics but is not identified as locally important agricultural land. The use of Farmland of Local Potential at this location would be temporary, lasting approximately 3 years. The land would be leased from the property owner during that time and would be restored to pre-existing condition and land uses following construction. Based on the preceding analysis, this temporary use would not result in the permanent conversion of Farmland to nonagricultural uses.

In addition, BMPs implemented during construction of the Ogier Ponds CM would protect agricultural land from direct damage or indirect disturbance that could result in conversion or loss of productivity. BMPs AQ-1 (dust control), BI-11 (minimize predator-attraction), and WQ-11 (maintain clean work sites) would require that work sites remain clean and do not attract pests or predators that could alter the agricultural environment. BMP WQ-4 (limit impacts from staging and stockpiling) would minimize impacts on staging and stockpiling areas. BMP TR-1 would require safety measures to assist agricultural producers and their equipment in avoiding traffic conflicts during construction. These BMPs would minimize the potential for construction of Conservation Measures to permanently convert Project Area Farmland to nonagricultural uses.

Throughout the construction of the Conservation Measures component, high flows that may occur within Coyote Creek may flood lands adjacent to the creek, and would have the potential to impact Farmland though the temporary inundation of these lands. Temporary inundation may lead to increased erosion or the destruction of crops within these Farmlands. Because the area of Farmlands located within a mile radius of the Conservation Measures component includes Prime Farmland, and Farmland of Local Importance, there may be a temporary conversion of these lands until waters recede. Therefore, these impacts would be minimal and short-term in nature, and would not permanently convert Farmland to a non-agricultural use.

Post-Construction Anderson Dam Facilities Operations

Following construction of the Project, Anderson Reservoir capacity would be restored to its existing (unrestricted) capacity and allowed to withstand a normal operational range of water levels in the reservoir. Post-construction releases from Anderson Reservoir into Coyote Creek would conform to FAHCE *Settlement Agreement* operating rule curves, as described in Chapter 2, *Project Description*. Furthermore, improved reliability of the dam structure would reduce the risk of a catastrophic failure that could affect the availability of agricultural water supplies throughout the region.

Table 3.11-8 in Section 3.11, *Hydrology*, shows that, under FAHCE conditions, the potential exists for increased frequency of minor flooding during 2-, 5-, and 10-year rainfall events, which could affect agricultural land, including Farmland, near the Project Area (Valley Water 2023). Flows would be lower than under existing conditions during greater-than-10-year rainfall events, however, and no modeling results indicated an exceedance of the 100-year flood level (15,000 cfs). The increased flow levels would be temporary and would not cause permanent conversion of Farmland. In addition, reservoir operations would utilize newly established access roads within the Seismic Retrofit component footprint, which would be located outside agricultural lands. Therefore, post-construction operations of Anderson Reservoir would not result in the conversion of Farmland to nonagricultural use.

Project and FAHCE Adaptive Management

The implementation of adaptive actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek Watershed, such as exotic species removal, replacement riparian planting, or additional sediment augmentation. These actions would occur when Conservation Measures components are not functioning as intended or not meeting measurable FAHCE measurable objectives. Adaptive actions would occur within Anderson Reservoir and Dam, and the Coyote Creek floodplain and would not be located on lands designated as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance.

Significance Conclusion Summary

As described above, areas of Farmlands are located outside the study area; however, 3.8 acres of Farmland of Local Potential southwest of the Ogier Ponds would be temporarily used for materials and equipment staging during the construction of the Ogier Ponds CM. Implementation of BMPs AQ-1 (dust control), BI-11 (minimize predator-attraction), WQ-4 (limit impacts from staging and stockpiling), WQ-11 (maintain clean work sites), and TR-1 (public safety measures) would help prevent permanent conversion of Farmland of Local Potential at this site. Post-construction operations associated with the retrofitted dam could result in minor flooding in some Farmland areas but would not rise to the level of conversion. Adaptive management actions, if required, would not take place in Farmland. Thus, the Project would not permanently convert areas of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural uses. The impact would therefore be **less than significant**.

Mitigation Measures

No mitigation is required.

Impact AG-2: Conflict with existing zoning for agricultural use or a Williamson Act contract **(Less than Significant)**

Seismic Retrofit Construction

Although the Project Area includes land that is currently zoned for grazing or agriculture, none of those lands are currently in active grazing or support large-scale agricultural production. Seismic Retrofit components construction would involve temporary construction activities (e.g., equipment and materials staging) on lands zoned for grazing and agricultural uses, specifically two parcels on Cochrane Road and one parcel along Coyote Creek immediately downstream of the dam, and temporary construction activities would not conflict with existing agricultural zoning. Therefore, construction of the Seismic Retrofit components would not result in the permanent conversion of land zoned agriculture to nonagricultural use or conflict with existing agricultural zoning.

BMPs implemented during Seismic Retrofit construction would also protect land zoned agriculture from direct damage or indirect disturbance that could result in conversion or loss of productivity. BMPs AQ-1 (dust control), BI-11 (minimize predator-attraction), and WQ-11 (maintain clean work sites) would require that work sites remain clean and do not attract pests or predators that could alter the agricultural environment. BMP WQ-4 (limit impacts from staging and stockpiling) would minimize impacts on staging and stockpiling areas. BMP TR-1 (public safety measures) would require safety measures to assist agricultural producers and their equipment in avoiding traffic conflicts during construction. These BMPs would minimize the potential for Seismic Retrofit construction to conflict with existing agricultural zoning in the study area.

In addition, there are no parcels under Williamson Act contract located within the Seismic Retrofit component Project Area, as shown in **Figure 3.2-1**. Therefore, Seismic Retrofit construction would not conflict with existing zoning for agricultural use or Williamson Act contracts.

Throughout the construction of the Seismic Retrofit component, high flows that may occur within Coyote Creek may flood lands zoned for agriculture or under Williamson Act Contracts adjacent to the creek. The inundation of these lands would conflict with agricultural land uses present in these areas. This temporary inundation may lead to increased erosion or the destruction of crops within these areas. However, these impacts would be minimal and short-term in nature, and would not permanently conflict with existing zoning for agricultural use or a Williamson Act contract.

Conservation Measures Construction

The Ogier Ponds CM area is currently zoned for exclusive agriculture, although the site is currently occupied by seasonal wetland ponds and used for recreational purposes; it is not under Williamson Act contract. Implementation of the Ogier Ponds CM would require the temporary use of 3.8 acres on the southwest side of Coyote Creek near Pond 1 for staging of construction equipment and import materials (**Figure 3.2-1b**). However, the use of lands at this location would be temporary, lasting approximately 3 years. The farmland would be leased from the property owner during that time and would be restored to its pre-existing condition following construction. Therefore, this temporary use would not conflict with existing zoning for agricultural use. In addition, implementation of BMPs AQ-1 (dust control), BI-11 (minimize predator-attraction), WQ-4 (limit impacts from staging and stockpiling), WQ-11 (maintain clean work sites), and TR-1 (public safety measures) would protect agricultural land in the study area from direct damage or indirect disturbance that could result in conflict with existing agricultural zoning.

Furthermore, the other Conservation Measures components, including the Maintenance of the North Channel Reach ~~Extension~~, Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach, Sediment Augmentation Program, and the Phase 2 Coyote Percolation Dam CM are not in areas currently zoned for agriculture and are not on parcels with Williamson Act contracts. Therefore, the use of these areas for Conservation Measure construction would not conflict with existing agricultural zoning or Williamson Act contracts.

Throughout the construction of the Conservation Measures component, high flows that may occur within Coyote Creek may flood lands zoned for agriculture or under Williamson Act Contracts adjacent to the creek. The inundation of these lands would conflict with agricultural land uses present in these areas. This temporary inundation may lead to increased erosion or the destruction of crops within these areas. However, these impacts would be minimal and short-term in nature, and would not permanently conflict with existing zoning for agricultural use or a Williamson Act contract.

Post-Construction Anderson Dam Facilities Operations

Project operations, described in the analysis of Impact AG-1 above, would occur within the Project Area outside agriculturally zoned areas or on lands under Williamson Act contracts. Proposed operational changes at Anderson Dam would not result in changes to agricultural zoning or affect the ability of parcels under Williamson Act contract to continue as a viable agricultural enterprise. Therefore, post-construction operations of Anderson Dam facilities would have no conflict with existing agricultural zoning or Williamson Act contracts.

Post-Construction Project and FAHCE Adaptive Management

The implementation of adaptive actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek Watershed, such as exotic species removal, replacement riparian plantings, or additional sediment augmentation. These actions would occur when post-construction dam operations or Conservation Measures are not functioning as intended or not meeting measurable FAHCE objectives. Adaptive actions would occur within Anderson Dam and Reservoir and the Coyote Creek floodplain, and would be located on lands zoned for agricultural use or under Williamson Act contract. Ogier Ponds is located in areas zoned as agricultural land use, and would be adaptively managed. However, there would be no conflict with existing agricultural zoning or Williamson Act contracts.

Significance Conclusion Summary

No lands under a Williamson Act contract are present within the study area; therefore, there would be no impacts to Williamson Act lands during construction or operation of the Project. Temporary construction activities within the Seismic Retrofit Project Area would not conflict with existing agricultural zoning. Lands zoned for agricultural use would be temporarily used for materials and equipment staging during the construction of the Ogier Ponds CM, but implementation of BMPs would minimize the potential for temporary impacts to conflict with existing zoning. Adaptive management actions, if required, would take place in agricultural areas. Ogier Ponds is located in area zoned as agricultural land uses and would be adaptively managed. However, the Project would not conflict with existing agricultural zoning or Williamson Act contracts, this impact would therefore be **less than significant**.

Mitigation Measures

No mitigation is required.

3.2.5 Cumulative Agricultural Resources

The geographic study area for the cumulative impact analysis for agricultural resources encompasses Santa Clara County. Most of the agricultural land in the northern end of the Santa Clara Valley has been converted from agricultural to urban uses. However, the southern end of the valley, including Coyote Valley has an active agricultural industry.

This section describes the Project's contribution to cumulative agricultural impacts, as summarized in **Table 3.2-4.**

Table 3.2-4. Summary of Project Impact Contribution to Cumulative Impacts on Agricultural Resources

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact AG-1: Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use	No	Yes	NCC	N/A	No
Cumulative Impact AG-2: Conflict with existing zoning for agricultural use or a Williamson Act contract	No	No	NCC	N/A	No

Key: N/A = not applicable; NCC = not cumulatively considerable

***Cumulative Impact AG-1: Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use* (Not Cumulatively Considerable)**

The Project would temporarily use 3.8 acres of Farmland of Local Potential southwest of the Ogier Ponds for materials and equipment staging during the construction of the Ogier Ponds CM. The Seismic Retrofit and other Conservation Measure components would not occur on farmland.

Cumulative projects, plans, and programs, such as Valley Water's other seismic retrofit, dam improvement, and flood protection projects, could result in incrementally adverse impacts if their construction or operations would reduce the amount, or effectiveness, of Prime or Unique Farmland, or Farmland of Statewide Importance within Santa Clara County.

Cumulative Effects of Project with the FOCP

The FOCP would involve modifications to the existing structures surrounding Anderson Dam and Reservoir but would not impact farmland. The FOCP combined with the Project would not result in cumulative impacts on agricultural resources.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Some private developments identified in Section 3.0.5, *Approach to Cumulative Impacts*, and other future projects to accommodate growth in south Santa Clara County, when combined with impacts of the Project, would result in impacts on Farmland. Because of the magnitude of agricultural land that has been converted in Santa Clara County and the ongoing pressure of farmland conversion in the state of California, the Project in combination with other probable future projects would result in a significant cumulative impact on agricultural resources.

Areas of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance are located outside of the Project area, except Prime Farmland located southwest of the Ogier Ponds that would be temporarily used for materials and equipment staging during the construction of the Ogier Ponds CM. After the completion of construction (about three years), the land would be restored to its original conditional and be available for agricultural uses. Valley Water would reduce the Project's incremental, short-term, contribution to cumulative impacts on Farmland through implementation of BMPs AQ-1 (dust control), BI-11 (minimize predator-attraction), WQ-4 (limit impacts from staging and stockpiling), WQ-11 (maintain clean work sites), and TR-1 (public safety measures), which would help prevent permanent conversion of Farmland at this site. The Project would have a minimal and less than significant impact on Farmland, and a less than cumulatively considerable contribution to cumulative impacts related to conversion of Farmland.

Significance Conclusion Summary

The total number of acres in agricultural production has been significantly reduced in Santa Clara historically. The Project would take 3.8 acres of farmland out of production during construction, but this land would not be permanently converted and would become available for agricultural use in the future. Cumulative impacts on Farmland would not be significant, and the Project's contribution to the conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use is **not cumulatively considerable.**

Mitigation Measure

No mitigation is required.

Cumulative Impact AG-2: Conflict with existing zoning for agricultural use or a Williamson Act contract **(Not Cumulatively Considerable)**

No lands under a Williamson Act contract are present within the study area; therefore, there would be no impacts to Williamson Act lands during construction or operation of the Project. There would be minimal potential for Seismic Retrofit and Ogier Pond Conservation Measure construction to conflict with agricultural zoning. The cumulative impact would not be significant, and the Project's contribution would not be cumulatively considerable.

Significance Conclusion Summary

No lands under a Williamson Act contract are present within the Project area, therefore the Project would not contribute to the cumulative impact. Cumulative impacts on land zoned agriculture would not be significant. The Project's contribution to cumulative impacts on Williamson Act contracts on land zone agriculture would be **not cumulatively considerable.**

3.3 Air Quality

This section provides information about applicable regulations related to air quality and the local air quality setting and evaluates air quality Project impacts, including pollutant emissions, health risks, and odors. The information in this section is based in part on the Anderson Dam Seismic Retrofit CEQA Air Quality, Greenhouse Gas and Health Risk Assessment Technical Report prepared by Ramboll US Consulting, Inc (Ramboll) in 2023 and updated in 2024, which is included in Appendix E[1].

The study area for air quality focuses on the portions of the County, San José, and Morgan Hill that comprise the Project Area, including the construction limits of the Seismic Retrofit and Conservation Measures components and the surrounding sensitive receptors, as well as the regional San Francisco Bay Area Air Basin (SFBAAB).

3.3.1 Environmental Setting

3.3.1.1 Air Pollutants

Several air pollutants of concern in the study area are described below. Two main categories of air pollutants are described: criteria air pollutants and toxic air contaminants (TAC). Criteria air pollutants are those air pollutants with national and/or state air quality standards that define allowable concentrations of these substances in the ambient air and typically affect air quality in terms of smog levels. TACs are those air pollutants identified that may lead to serious illness or increased mortality, even when present in relatively low concentrations.

Criteria Air Pollutant Types, Sources, and Effects

The following descriptions are of sources and effects of the primary criteria air pollutants.

Carbon Monoxide

Carbon monoxide (CO) is an odorless, colorless gas that is highly toxic. CO is formed by the incomplete combustion of fuels and is emitted directly into the air. Ambient CO concentrations normally are considered a local effect and typically correspond closely to the spatial and temporal distributions of vehicular traffic. CO concentrations are also influenced by wind speed and atmospheric mixing. Under inversion conditions, CO concentrations may be distributed more uniformly over an area to some distance from vehicular sources. CO binds with hemoglobin, the oxygen-carrying protein in blood, and reduces the blood's capacity for carrying oxygen to the heart, brain, and other parts of the body. At high concentrations, CO can cause heart difficulties in people with chronic diseases, impair mental abilities, and cause death.

Ozone

Ozone is a reactive gas consisting of three oxygen atoms. In the troposphere (the lowest region of the atmosphere), it is a product of the photochemical process involving the sun's energy. It is a secondary pollutant that is formed when nitrogen oxides (NO_x) and reactive organic gases

[1] Appendix E has been revised in support of the Final EIR.

(ROG) react in the presence of sunlight. Ozone at the earth's surface causes numerous adverse health effects and is a criteria pollutant. It is a major component of smog. In the stratosphere, ozone exists naturally and shields the Earth from harmful incoming ultraviolet radiation. High concentrations of ground-level ozone can adversely affect the human respiratory system and aggravate cardiovascular disease and many respiratory ailments. Ozone also damages natural ecosystems, such as forests and foothill communities, agricultural crops, and some man-made materials, such as rubber and plastics.

Nitrogen Oxides

NO_x are a family of gaseous nitrogen compounds and are precursors to the formation of ozone and particulate matter (PM). The major component of NO_x, nitrogen dioxide (NO_2), is a reddish-brown gas that is toxic at high concentrations. NO_x result primarily from the combustion of fossil fuels under high temperature and pressure. On-road and off-road motor vehicles and fuel combustion are the major sources of this air pollutant. NO_2 can decrease lung function and may reduce resistance to infection.

Reactive Organic Gases

ROGs are hydrocarbon compounds that exist in the ambient air. ROGs contribute to the formation of smog and/or may themselves be toxic. ROG emissions are a major precursor to the formation of ozone. Individual ROGs can be TACs.

Particulate Matter

PM is a complex mixture of extremely small particles and liquid droplets. PM is made up of a number of components, including acids, organic chemicals, metals, and soil or dust particles. The size of particles is directly linked to the potential for causing health problems. PM particles that are smaller than 10 micrometers in diameter, called PM_{10}, are of most concern because these particles pass through the throat and nose and enter the lungs. Once inhaled, these particles can affect the heart and lungs and cause serious health effects. PM_{10} particles are typically found near roadways and dusty industries. PM_{10} particles are deposited in the thoracic region of the lungs. Fine particles, called $PM_{2.5}$, are particles less than 2.5 micrometers in diameter and are found in smoke and haze. $PM_{2.5}$ particles penetrate deeply into the thoracic and alveolar regions of the lungs.

PM can be emitted directly from primary sources or formed secondarily from reactions in the atmosphere. Primary sources include windblown dust, grinding operation, smokestacks, and fires. Secondary formation of PM occurs from reactions of gaseous precursors within the atmosphere, such as the formation of nitrates from NO_x emissions from combustion activities.

PM can accumulate in the respiratory system and aggravate health problems. These health effects include cardiovascular symptoms; cardiac arrhythmias; heart attacks; respiratory symptoms; asthma attacks; bronchitis; alterations in lung tissue, lung structure, and respiratory tract defense mechanisms; and premature death in people with heart or lung disease. Those at particular risk of increased health decline from exposure to PM include people with preexisting heart or lung disease, children, and seniors.

Sulfur Dioxide

Sulfur dioxide (SO_2) is a colorless, irritating gas with a “rotten egg” smell formed primarily by the combustion of sulfur-containing fossil fuels. Suspended SO_2 particles contribute to the poor visibility that occurs in the SFBAAB and are a component of PM_{10}. SO_2 irritates the respiratory tract, can injure lung tissue when combined with fine PM, and reduces visibility and the level of sunlight.

Lead

Lead is a metal that is a natural constituent of air, water, and the biosphere. Lead is neither created nor destroyed in the environment, so it essentially persists forever. The health effects of lead poisoning include loss of appetite, weakness, apathy, and miscarriage. Lead poisoning can also cause lesions of the neuromuscular system, circulatory system, brain, and gastrointestinal tract.

Gasoline-powered automobile engines were a major source of airborne lead using leaded fuels. The use of leaded fuel has been mostly phased out, which has resulted in dramatic drops in ambient concentrations of lead.

Hydrogen Sulfide

Hydrogen sulfide (H_2S) is associated with geothermal activity, oil and gas production, refining, sewage treatment plants, and confined animal feeding operations. H_2S is extremely hazardous in high concentrations and can cause death.

Sulfates

Sulfates are the fully oxidized ionic form of sulfur. Sulfates occur in combination with metal and/or hydrogen ions. In California, emissions of sulfur compounds occur primarily from the combustion of petroleum-derived fuels (e.g., gasoline and diesel fuel) that contain sulfur. This sulfur is oxidized to SO_2 during the combustion process and subsequently converted to sulfate compounds in the atmosphere. The conversion of SO_2 to sulfates takes place comparatively rapidly and completely in urban areas of California due to regional meteorological features.

California Air Resources Board’s (CARB) sulfate standard is designed to prevent aggravation of respiratory symptoms. Effects of sulfate exposure at levels above the standard include a decrease in ventilatory function, aggravation of asthmatic symptoms, and an increased risk of cardio-pulmonary disease. Sulfates are particularly effective in degrading visibility, and, since they are usually acidic, can harm ecosystems and damage materials and property.

Toxic Air Contaminant Types, Sources, and Effects

Sources of TACs include stationary sources, area-wide sources, and mobile sources. The USEPA maintains a list of 187 TACs, also known as hazardous air pollutants. These hazardous air pollutants are included on CARB’s list of TACs (CARB 2021). TAC emissions include diesel PM (DPM) from diesel-fueled vehicles and various TACs contained in gasoline exhaust and evaporative emissions, including 1,3-butadiene, acetaldehyde, acrolein, benzene, ethylbenzene, formaldehyde, hexane, methanol, methyl ethyl ketone, naphthalene, propene, styrene, toluene, and xylenes. Various metals that are TACS are contained in the fugitive dust that can be generated from blasting, including arsenic, barium, beryllium, cadmium, cobalt, hexavalent chromium, copper, mercury, molybdenum, nickel, lead, silver, vanadium, and zinc. According to the California Almanac of Emissions and Air Quality (CARB 2013), many researchers consider DPM to be a primary contributor to health risk from TACs, because particles in the exhaust carry many harmful organics and metals rather than being a single substance as are other TACs. Unlike many TACs, outdoor DPM is not monitored by CARB, because no routine measurement method exists. However, using the CARB emission inventory's PM_{10} database, ambient PM_{10} monitoring data, and results from several studies, CARB has made preliminary estimates of DPM concentrations throughout the state (California Office of Environmental Health Hazard Assessment [OEHHA] 2001). Naturally occurring asbestos (NOA) is discussed in Section 3.10, *Hazards and Hazardous Materials*.

Hundreds of different types of TACs exist, with varying degrees of toxicity. Many TACs are confirmed or suspected carcinogens or are known or suspected to cause birth defects or neurological damage. For some chemicals, such as carcinogens, no thresholds exist below which exposure can be considered risk-free.

3.3.1.2 Regional Air Quality

Local control in air quality management is provided by CARB through county-level or regional (multi-county) air districts. CARB establishes statewide air quality standards and is responsible for control of mobile emission sources, while the local air districts are responsible for enforcing standards and regulating stationary sources. CARB has established 15 air basins statewide. The Project Area is located in the SFBAAB, which is under the jurisdiction of the Bay Area Air Quality Management District (BAAQMD).

San Francisco Bay Area Air Basin – Santa Clara Valley Subregion

The SFBAAB geographic area is characterized by a complex terrain consisting of coastal mountain ranges, inland valleys, and bays, which distort normal wind flow patterns. The Coast Ranges split, resulting in a western coast gap (the Golden Gate) and an eastern coast gap (the Carquinez Strait), both of which allow air to flow into and out of the SFBAAB and the Central Valley.

BAAQMD divides the SFBAAB into subregions with distinct climates and topographic features. The Project Area is located in the Santa Clara Valley Subregion of the SFBAAB. The Santa Clara Valley Subregion is bounded by the San Francisco Bay to the north and by mountains to the east, south, and west. Temperatures are warm on summer days and cool on summer nights, and winter temperatures are fairly mild. At the northern end of the valley, mean maximum temperatures are in the low 80s (all temperatures are in degrees Fahrenheit [°F]) during the summer and the high 50s during the winter, and mean minimum temperatures range from the high 50s in the summer to the low 40s in the winter. Further inland, where the moderating effect of the Bay is not as strong, temperature extremes are greater.

Winds in the Santa Clara Valley are greatly influenced by the terrain, resulting in a prevailing flow that roughly parallels the Valley's northwest–southeast axis. A north-northwesterly sea breeze flows through the Valley during the afternoon and early evening, and a light south southeasterly flow occurs during the late evening and early morning. In the summer, the southern end of the Valley sometimes becomes a "convergence zone," when air flowing from Monterey Bay is channeled northward into the southern end of the Valley and meets with the prevailing north-northwesterly winds.

Wind speeds are greatest in the spring and summer and weakest in the fall and winter. Nighttime and early morning hours frequently have calm winds in all seasons, while summer afternoons and evenings are breezy. Strong winds are rare, associated mostly with the occasional winter storm.

The air pollution potential of the Santa Clara Valley is high. High summer temperatures, stable air, and mountains surrounding the valley combine to promote ozone formation. Ozone is an air pollutant that is not typically emitted directly from sources but is formed in the atmosphere from the interaction of light, oxygen, and ozone precursors, such as NO_x and ROGs. In addition to the many local sources of pollution, ozone precursors from San Francisco, San Mateo, and Alameda Counties are carried by prevailing winds to the Santa Clara Valley. The Valley tends to channel pollutants toward the southeast, where the Project Area is located. In addition, on summer days with low-level inversions, ozone can be recirculated by southerly flows in the late evening and early morning and by the prevailing northwesterly winds in the afternoon. A similar recirculation pattern occurs in the winter, affecting levels of CO and PM. This movement of the air up and down the valley substantially increases the impact of air pollutant emissions (BAAQMD 2017a ~~2017c~~).

Pollution Sources in the Santa Clara Valley Subregion

Pollution sources are complex in the Santa Clara Valley subregion. The Santa Clara Valley has a high concentration of industrial activities in the northern area known as Silicon Valley. Some of these industrial activities are sources of TACs and criteria air pollutants. In addition, the Santa Clara Valley's large population and many work-site destinations generate the highest mobile-source emissions of any subregion in the SFBAAB (BAAQMD 2017a ~~2017c~~).

Air Pollutant Attainment Designations for SFBAAB

Both the USEPA and CARB use ambient air quality monitoring data to designate areas according to their attainment status for criteria air pollutants. The purpose of these designations is to identify the areas with air quality problems and initiate planning efforts for improvement. The three basic designation categories are nonattainment, attainment, and unclassified. “Attainment” status refers to those regions that are meeting federal and/or state standards for a specified criteria pollutant. “Nonattainment” refers to regions that do not meet federal and/or state standards for a specified criteria pollutant. “Unclassified” refers to regions where there is not enough data to determine the region’s attainment status for a specified criteria air pollutant.

Table 3.3-1 shows the current attainment status for National Ambient Air Quality Standards (NAAQS) and California Ambient Air Quality Standards (CAAQS) in the SFBAAB. The SFBAAB, including the Santa Clara Valley subregion and Project Area, is currently designated as a state and federal non-attainment area for ozone and $PM_{2.5}$, and a state nonattainment area for PM_{10} (BAAQMD 2017b ~~2017a~~). The SFBAAB is unclassified or classified as attainment for all other pollutant standards.

Table 3.3-1. State and Federal Ambient Air Quality Standards and SFBAAB Attainment Status

Pollutant	Averaging Time	State (CAAQS A)		Federal (NAAQS B)	
		Standard	**Standard**	**Standard**	**Attainment Status**
Ozone	1-hour	0.09 ppm	N	NA	See Note C
	8-hour	0.070 ppm	N	0.070 ppm [D]	**N**; see Note E
Carbon Monoxide (CO)	1-hour	20 ppm	A	35 ppm	A
	8-hour	9 ppm	A	9 ppm	A
Nitrogen Dioxide (NO_2)	1-hour	0.18 ppm	A	0.100 ppm	A; see Note F
	Annual	0.030 ppm	U	0.053 ppm	A
Sulfur Dioxide (SO_2)	1-hour	0.25 ppm	A	0.075 ppm	U/A; see Note G
	24-hour	0.04 ppm	A	0.14 ppm	U/A; see Note G
	Annual	NA	NA	0.03 ppm	U/A; see Note G
Particulate Matter (PM_{10})	24-hour	50 $\mu g/m^3$	N	150 $\mu g/m^3$	U
	Annual [H]	20 $\mu g/m^3$	N [I]	NA	NA
Fine Particulate Matter ($PM_{2.5}$)	24-hour	NA	NA	35 $\mu g/m^3$	N; see Note M
	Annual	12 $\mu g/m^3$	N [I]	12 $\mu g/m^3$ [O]	U/A
Sulfates	24-hour	25 $\mu g/m^3$	A	NA	NA
Lead[K]	30-day	1.5 $\mu g/m^3$	A	NA	A
	Cal. Quarter	NA	NA	1.5 $\mu g/m^3$	A
	Rolling 3-month average	NA	NA	0.15 –	U; see Note J
Hydrogen Sulfide	1-hour	0.03 ppm	U	NA	NA
Vinyl Chloride[K] (chloroethene)	24-hour	0.010 ppm	No information available	NA	NA
Visibility-Reducing Particles	8-hour	See Note L	U	NA	NA

Sources: BAAQMD 2017b ~~2017a~~, USEPA 2020.

Notes:

[A] CAAQS for ozone, CO (except Lake Tahoe), SO_2 (1 hour and 24 hour), NO_2, PM, and visibility reducing particles are values that are not to be exceeded. All other state standards shown are values not to be equaled or exceeded.

[B] NAAQS, other than ozone and particulates, and those based on annual averages or annual arithmetic means, are not to be exceeded more than once a year. The 1-hour ozone standard is attained if, during the most recent 3-year period, the average number of days per year with maximum hourly concentrations above the standard is equal to or less than 1. The 8-hour ozone standard is attained when the 3-year average of the fourth highest daily concentration is 0.070 ppm or less. The 24-hour PM_{10} standard is attained when the 3-year average of the 99th percentile of monitored concentrations is less than the standard. The 24-hour $PM_{2.5}$ standard is attained when the 3-year average of the 98th percentile is less than the standard.

[C] The USEPA revoked the national 1-hour ozone standard on June 15, 2005.

[D] This federal 8-hour ozone standard was approved by USEPA in October 2015 and became effective on December 28, 2015.

[E] On October 1, 2015, the national 8-hour ozone primary and secondary standards were lowered from 0.075 to 0.070 ppm. An area will meet the standard if the fourth-highest maximum daily 8-hour ozone concentration per year, averaged over 3 years, is equal to or less than 0.070 ppm. USEPA made recommendations on attainment designations for California by October 1, 2016, and issued final designations on June 4, 2018, classifying the San Francisco Bay Area Air Basin as being in nonattainment (Federal Register Vol. 83, No. 107, pp. 25776-25848). Nonattainment areas will have until 2020 to 2037 to meet the health standard, with attainment dates varying based on ozone level in the area.

[F] To attain this standard, the 3-year average of the 98th percentile of the daily maximum 1-hour average at each monitor within an area must not exceed 0.100 ppm (effective January 22, 2010).

[G] On June 2, 2010, the USEPA established a new 1-hour SO_2 standard, effective August 23, 2010, which is based on the 3-year average of the annual 99th percentile of 1-hour daily maximum concentrations. The existing 0.030 ppm annual and 0.14 ppm 24-hour SO_2 NAAQS however must continue to be used until one year following USEPA initial designations of the new 1-hour SO_2 NAAQS. USEPA classified the San Francisco Bay Area Air Basin as being in attainment/unclassifiable in January 2018 (Federal Register Vol. 83, No. 6, pp. 1098-1172).

[H] State standard = annual geometric mean

[I] In June 2002, CARB established new annual standards for $PM_{2.5}$ and PM_{10}.

[J] National lead standard, rolling 3-month average: final rule signed October 15, 2008. Final designations effective December 31, 2011.

[K] CARB has identified lead and vinyl chloride as toxic air contaminants with no threshold level of exposure below which there are no adverse health effects determined.

[L] Statewide visibility reducing particle standard (except Lake Tahoe Air Basin): Particles in sufficient amount to produce an extinction coefficient of 0.23 per kilometer when the relative humidity is less than 70 percent. This standard is intended to limit the frequency and severity of visibility impairment due to regional haze and is equivalent to a 10-mile nominal visual range.

[M] On January 9, 2013, USEPA issued a final rule, determining that SFBAAB has attained the 24-hour $PM_{2.5}$ national standard. This rule suspends key State Implementation Plan requirements as long as monitoring data continues to show that SFBAAB attains the standard. Despite this USEPA action, SFBAAB will continue to be designated as "nonattainment" for the national 24-hour $PM_{2.5}$ standard until BAAQMD submits a "redesignation request" and a "maintenance plan" to USEPA, and USEPA approves the proposed redesignation.

[O] On February 7, 2024, USEPA lowered the NAAQS for fine particle pollution (PM2.5) by revising the level of the primary (health-based) annual PM2.5 standard to 9.0 µg/m3. The effective date of the new standard was May 6, 2024. However, the 12.0 µg/m3 standard was the standard at the time of Draft EIR preparation.

Key: A = Attainment; CAAQS = California Ambient Air Quality Standards; NAAQS = National Ambient Air Quality Standards; N = Non-attainment; U = Unclassified; NA = Not Applicable, no applicable standard; ppm = parts per million; µg/m3 = micrograms per cubic meter

TACs in the SFBAAB

The BAAQMD prepares a detailed annual inventory of TAC emissions from permitted stationary sources. The BAAQMD's Community Air Risk Evaluation (CARE) program provides toxicity-weighted estimates of total TAC emissions from all sources, including on-road and off-road mobile sources, and this program provides a better understanding of the contributions to public health impacts from TACs than the detailed annual inventory. The BAAQMD estimated that 50 percent of the Bay Area population is estimated to have an ambient background inhalation cancer risk of less than 500 cases in 1 million (BAAQMD 2023a). DPM is the most impactful TAC in the Bay Area, accounting for roughly 85 percent of the cancer risk from air toxics in the region (BAAQMD 2023a).

3.3.1.3 Valley Water and Anderson Dam

Ambient Air Quality Monitoring Data

The USEPA, CARB, and local air districts (including the BAAQMD) operate an extensive air monitoring network to measure progress toward attainment of the NAAQS and CAAQS. **Table 3.3-2** shows the most recent 3 years of available data available at the time of Draft EIR preparation. The closest station to the Project Area with data for all six criteria pollutants is the San José-Jackson Street station.

Table 3.3-2. Ambient Air Quality Monitoring Data for 2019-2021 ~~2017-2019~~, San José-Jackson Street Monitoring Station

Pollutant	State/Federal Standards	2019		2020		2021	
		No. Exceed[1]	Max Conc	No. Exceed[1]	Max Conc	No. Exceed[1]	Max Conc

Notes:

[1.] Indicates the number of exceedance days recorded annually at this monitoring station for a particular constituent compared to that constituent's CAAQS and NAAQS, respectively. The first number is the state value, and the second number is the federal value if they are different.

*Key: CO = carbon monoxide; NO_2 = nitrogen dioxide; $PM_{2.5}$ = particulate matter of 2.5 micrometers or less; PM_{10} = particulate matter of 10 micrometers or less; SO_2 = sulfur dioxide; NA = not available; ppb = parts per billion; ppm = parts per million; µg/m³ = micrograms per cubic meter; * = insufficient data available to determine the value.*

Odors

Odors in the study area are generally not a concern. Based on a public records data request, the area within 1,000 feet of the Project Area has no odor complaints (BAAQMD 2023b ~~2023a~~).

Air Pollution Sensitive Receptors

The term "sensitive receptors" refers to those segments of the population most susceptible to poor air quality and various air pollutants: children, the elderly, and individuals with pre-existing, serious health problems affected by such air pollutants (CARB 2005). Examples of sensitive receptor locations are residences, schools and school yards, parks and playgrounds, daycare centers, nursing homes, and medical facilities.

Existing land uses within and adjacent to the Project Area include Coyote Creek, parkland and hiking trails, the Anderson Reservoir boat ramp, the Anderson Lake County Park Visitor's Center, the Santa Clara County Justice Training Center, the William F. James Boys Ranch, an orchard, and private residences. As such, sensitive receptor locations in the Project Area include residential communities, a high school, and public parkland, where sensitive receptors may reside or regularly visit.

Sensitive receptors in the Project Area are described below by Project component, with haul routes described separately.

Anderson Dam

Anderson Dam is located in the midst of the Anderson Lake County Park. Sensitive receptors flank the western and southern portions of Anderson Dam, while the areas north and east of Anderson Dam are undeveloped. Receptors located near where seismic retrofit construction work would occur include the residential community along Holiday Drive immediately adjacent to Anderson Dam to the southwest, the residential community south of Anderson Lake County Park, located south and west of Cochrane Road, and receptors at Anderson Lake County Park and Rosendin Park, both located south of the seismic retrofit construction areas. Blue Ridge High School and the William F. James Boys Ranch, a juvenile detention center, are located immediately north of the Project's construction area downstream of Anderson Dam, across Coyote Creek. The William F. James Boys Ranch serves as both a residence and school and is therefore identified as a sensitive receptor location. Live Oak High School is approximately 1 mile south of Anderson Dam, located along East Main Street in Morgan Hill. The closest licensed elder care facility is the Westmont of Morgan Hill care facility, which is approximately 1 mile southwest of Anderson Dam along Cochrane Road (Community Care Licensing Division [CCLD] 2021). The nearest medical facility is Morgan Hill Medical Associates, approximately 1 mile south of the Project Area along Depaul Drive in Morgan Hill. The CCLD website also identifies multiple child and infant care centers in Morgan Hill. Most of these facilities are located west of US 101, approximately 1.3 miles west of the Project Area.

Ogier Ponds

The Ogier Ponds are situated in the midst of an underdeveloped area that is predominantly industrial with pockets of residential uses. The closest sensitive receptor to the Ogier Ponds CM area is the Parkway Lakes Recreation Vehicle (RV) Park located southwest of the Ogier Ponds along the east side of Monterey Highway, adjacent to the Project Area. Other notable sensitive receptors include Sobrato High School, located approximately 1.2 miles to the southeast along the north side of Burnett Avenue.

Maintenance of the North Channel ~~Extension~~ Reach and Live Oak Restoration Reach

Maintenance of the ~~The~~ North Channel ~~Extension~~ Reach and Live Oak Restoration Reach are located downstream of Anderson Dam along Coyote Creek. Nearby sensitive receptors include residential communities adjacent to Coyote Creek to the south of Cochrane Road and Malaguerra Avenue.

Sediment Augmentation Program

The Sediment Augmentation Conservation Program spans the length of Coyote Creek downstream of Anderson Dam to Ogier Ponds. Nearby sensitive receptors include those nearby the Maintenance of the North Channel ~~Extension~~ Reach and Live Oak Restoration Reach Conservation Measures, discussed above, and residential communities southwest of Coyote Creek bound by US 101 to the northeast and Monterey Highway to the southwest.

Phase 2 Coyote Percolation Pond

The Phase 2 Coyote Percolation Pond CM area is bound by Monterey Highway to the southwest, US 101 to the northeast, and Metcalf Road to the southeast. The closest receptors include residential communities adjacent to Coyote Percolation Pond to the south and west and Metcalf Park adjacent to the south. Residential communities are also located north of US101, approximately 0.1 miles from the Project Area.

Haul Routes

Sensitive receptors along construction haul routes include the following:

- Cochrane Road: Sensitive receptors (single-family residential) line both sides of Cochrane Road between the Cochrane Road and Mission View Drive intersection and the Malaguerra Avenue and Cochrane Avenue intersection.

- Malaguerra Avenue: Sensitive receptors located along Malaguerra Avenue include the residential neighborhood located southwest of Malaguerra Avenue and northwest of Cochrane Road.
- Dunne Avenue: Sensitive receptors are located along Dunne Avenue from the Murphy Road and Dunne Avenue intersection and extending to the northeast. The predominant receptors abutting both sides of Dunne Avenue include single-family residential uses. Other sensitive receptors fronting Dunne Avenue include Nordstrom Park, Nordstrom Elementary School, and The Church of Jesus Christ of Latter-day Saints, and several smaller parks.
- Hill Road: Sensitive receptors (i.e., single-family residential) are located along both sides of Hill Road.
- Main Avenue: Sensitive receptors (i.e., single-family residential and Live Oak High School) are located along both sides of Main Avenue.

3.3.2 Regulatory Setting

3.3.2.1 Federal Laws, Regulations, and Policies

Clean Air Act and National Ambient Air Quality Standards

The Clean Air Act is implemented by the USEPA and sets ambient air emission limits, referred to as NAAQS, for six criteria air pollutants: PM_{10}, $PM_{2.5}$, CO, NO_2, ozone, and lead.

Table 3.3-1 shows the current attainment status for NAAQS and CAAQS in the SFBAAB (study area).

The USEPA and CARB regulate various stationary sources, area sources, and mobile sources of air pollutant emissions. The USEPA has regulations involving performance standards for specific sources that may release TACs, known at the federal level as hazardous air pollutants (HAP). In addition, the USEPA has regulations involving emission criteria for off-road air emission sources such as emergency generators, construction equipment, and vehicles; the USEPA also regulates releases of toxic chemicals.

USEPA and NHTSA Emission Standards for On-Road Vehicles

In 1975, Congress enacted the Energy Policy and Conservation Act, which established the first fuel economy standards for on-road motor vehicles in the United States. Pursuant to the act, the USEPA and National Highway Traffic Safety Administration (NHTSA) are responsible for establishing additional vehicle standards. In August 2012, standards were adopted for model year 2017 through 2025 for passenger cars and light-duty trucks. Notably, California harmonized its vehicle efficiency standards through 2025 with the federal standards through the Advanced Clean Cars Program.

In March 2022, Corporate Average Fuel Economy (CAFE) standards were finalized for model years 2024 through 2026. The final rule establishes standards that require an industry-wide fleet average of approximately 49 miles per gallon for passenger cars and light trucks. Current rulemaking is working on establishing (NHTSA 2022):

- standards for model years 2027 and beyond for passenger cars and light trucks

- fuel efficiency standards for model years 2029 and beyond for heavy-duty pickup trucks and vans
- fuel efficiency standards for model years 2030 and beyond for medium and heavy duty on-highway vehicles and work trucks

USEPA Emission Standards for Nonroad Equipment and Vehicles

The USEPA has adopted emission standards for different types of non-road engines, equipment, and vehicles. For nonroad diesel engines, the USEPA has adopted multiple tiers of emission standards.

The USEPA signed a final rule on May 11, 2004, introducing the Tier 4 emission standards, to be phased in between 2008 and 2015 (69 Code of Federal Regulations (CFR) 38957–39273, June 29, 2004). The Tier 4 standards require that emissions of PM and NO_X be further reduced by about 90 percent. Such emission reductions can be achieved through the use of control technologies, including advanced exhaust gas after-treatment. To enable sulfur-sensitive control technologies in Tier 4 engines, the USEPA also mandated reductions in sulfur content in nonroad diesel fuels. In most cases, federal nonroad regulations also apply in California, which has only limited authority to set emission standards for new nonroad engines. The Clean Air Act preempts California's authority to control emissions from new farm and construction equipment less than 175 horsepower (hp) (Clean Air Act Section 209[e][1][A]) and requires California to receive authorization from the USEPA for controls over other off-road sources (Clean Air Act Section 209[e][2][A]). New engines built in and after 2015 across all hp sizes must meet Tier 4 final emission standards. In other words, new manufactured engines cannot exceed the emissions established for Tier 4 final emissions standards.

3.3.2.2 State Laws, Regulations, and Policies

California Clean Air Act and Ambient Air Quality Standards

CARB sets standards for criteria pollutants in California that are more stringent than the NAAQS and include the following additional contaminants: visibility-reducing particles, H_2S, sulfates, and vinyl chloride. **Table 3.3-1** provides the CAAQS and their corresponding attainment status in the SFBAAB. The BAAQMD has the responsibility to monitor ambient air pollutant levels throughout the SFBAAB and to develop and implement strategies to attain the applicable federal and state standards.

CARB is responsible for setting emission standards for vehicles sold in California and for other emission sources, such as consumer products and certain off-road equipment. CARB also establishes passenger vehicle fuel specifications.

CARB Emission Standards for In-use Off-road Diesel Vehicles

In 2007, CARB adopted a regulation to reduce DPM and NO_X emissions from in-use, off-road, heavy-duty diesel vehicles in California. The regulation imposes limits on vehicle idling and requires fleets to reduce emissions by retiring, replacing, repowering, or installing exhaust retrofits to older engines. In December 2011, the regulation was amended to modify the compliance dates for performance standards and establish requirements for compliance with verified diesel emission control strategy technologies that reduce PM and/or NO_X emissions. The regulation is in the process of finalizing additional amendments that will require the phase out of the oldest and highest emitting off-road engines and would restrict the addition of vehicles with Tier 3 and Tier 4 interim engines. The rules would be implemented starting in 2024 and would require contracting entities to obtain and retain a fleet's valid Certificate of Reported Compliance prior to awarding a contract or hiring a fleet, mandate the use of R99 or R100 Renewable Diesel for all fleets with some limited exceptions, and provide additional requirements to increase enforceability and provide flexibility for permanent low-use vehicles.

CARB Emission Standards for Trucks and Buses

In 2008, CARB approved a regulation to substantially reduce emissions of DPM, NO_X, and other pollutants from existing on-road diesel vehicles operating in California. The regulation requires affected trucks and buses to meet performance standards and requirements by 2023. Affected vehicles include on-road, heavy-duty, diesel-fueled vehicles with a gross vehicle weight rating greater than 14,000 pounds. The regulation was updated in 2011 and 2014 to provide more compliance flexibility and reflect the impact of the 2008 economic recession on vehicle activities and emissions.

CARB Emission Standards for Heavy-duty On-board Diagnostic Systems

In 2004, CARB adopted regulations requiring on-board diagnostic (OBD) systems on all 2007 and later model year heavy-duty engines and vehicles (i.e., vehicles with a gross vehicle weight rating greater than 14,000 pounds) in California. CARB subsequently adopted a comprehensive OBD regulation for heavy-duty vehicles model years 2010 and beyond. The heavy-duty OBD regulations were updated in 2010, 2013, and 2016 with revisions to enforcement requirements, testing requirements, and implementation schedules. Heavy-duty trucks used during Project construction or operations would be required to comply with the heavy-duty OBD regulatory requirements.

CARB Inspection Program for Heavy-duty Vehicles

The heavy-duty vehicle inspection program requires heavy-duty trucks and buses to be inspected for excessive smoke and tampering and for compliance with engine certification labels. Any heavy-duty vehicle (i.e., a vehicle with a gross vehicle weight rating greater than 14,000 pounds) traveling in California, including vehicles registered in other states and foreign countries, may be tested. Tests are performed by CARB inspection teams at border crossings, California Highway Patrol weigh stations, fleet facilities, and randomly selected roadside locations. Owners of trucks and buses found to be in violation are subject to penalties starting at $300 per violation. Heavy-duty trucks used during Project construction or operations would be subject to the inspection program.

CARB Clean Cars Programs

The Advanced Clean Cars emissions-control program was approved by CARB in 2012 and is closely associated with the Pavley regulations (CARB 2017~~a~~). The program requires a greater number of zero-emission vehicle models for years 2015 through 2025 to control smog, soot, and GHG emissions. This program includes the low-emissions vehicle (LEV) regulations to reduce criteria pollutants and GHG emissions from light- and medium-duty vehicles and the ZEV regulations to require manufactures to produce an increasing number of pure ZEV's (meaning battery and fuel cell electric vehicles) with the provision to produce plug-in hybrid electric vehicles (PHEV) between 2018 and 2025.

California recently adopted the new Advanced Clean Car II in August 2022, which dramatically reduces emissions from passenger vehicles for model years 2026 through 2035. Advanced Clean Cars II would require more aggressive tailpipe emission standards for gasoline cars and heavier passenger trucks and require all new vehicles sold by 2035 be ZEVs (CARB 2023a ~~2023c~~).

CARB Mobile Source Strategy

The Mobile Source Strategy (2016) includes an expansion of the Advanced Clean Cars program and further increases the stringency of GHG emissions for all light-duty vehicles, and 4.2 million zero-emission and plug-in hybrid light-duty vehicles by 2030. It also calls for more stringent GHG requirements for light-duty vehicles beyond 2025 as well as GHG reductions from medium-duty and heavy-duty vehicles and increased deployment of zero-emission trucks primarily for classes 3 through 7 "last mile" delivery trucks in California. Statewide, the Mobile Source Strategy would result in a 45 percent reduction in GHG emissions and a 50 percent reduction in the consumption of petroleum-based fuels. CARB's Mobile Source Strategy includes measures to reduce total light-duty vehicle miles travelled (VMT) by 15 percent compared to business-as-usual in 2050.

CARB Regulations on Diesel Emissions

In 2004, the CARB adopted an ATCM to Limit Diesel-Fueled Commercial Motor Vehicle Idling in order to reduce public exposure to diesel particulate matter emissions (Title 13 CCR Section 2485). The measure applies to diesel-fueled commercial vehicles with gross vehicle weight ratings greater than 10,000 pounds that are licensed to operate on highways, regardless of where they are registered. This measure does not allow diesel-fueled commercial vehicles to idle for more than 5 minutes at any given location. While the goal of this measure is primarily to reduce public health impacts from diesel emissions, compliance with the regulation also results in energy savings in the form of reduced fuel consumption from unnecessary idling.

In addition to limiting exhaust from idling trucks, CARB also promulgated emission standards for off-road diesel construction equipment of greater than 25 hp such as bulldozers, loaders, backhoes and forklifts, as well as many other self-propelled off-road diesel vehicles. The In-Use Off-Road Diesel-Fueled Fleets regulation adopted by CARB on July 26, 2007 aims to reduce emissions through the installation of diesel soot filters and encouraging the retirement, replacement, or repower of older, dirtier engines with newer emission-controlled models (13 CCR Section 2449). The compliance schedule requires full implementation by 2023 in all equipment for large and medium fleets and by 2028 for small fleets. Current rulemaking of this regulation anticipated to be finalized in 2023 includes additional updates to ensure fleet compliance by requiring public agencies and prime contractors to verify compliance with these fleet requirements annually and to report non-compliant fleets. In addition, starting in 2024, fleets will be required to use 99 or 100 renewable diesel.

California Standards for Diesel Fuel Regulations

The California Standards for Diesel Fuel Regulations require diesel fuel with a sulfur content of 15 parts per million (ppm) or less (by weight) to be used for all diesel-fueled vehicles that are operated in California. The standard also applies to non-vehicular diesel fuel, other than diesel fuel used solely in locomotives or marine vessels. The regulations also contain standards for the aromatic hydrocarbon content and lubricity of diesel fuels.

Assembly Bill 1346: Air Pollution: small off-road engines

AB 1346 requires CARB to adopt cost-effective and technologically feasible regulations to prohibit engine exhaust and evaporative emissions from new Small Off-Road Engines (SORE) by July 1, 2022, for engines produced on or after January 1, 2024, or as soon as CARB determines is feasible. In determining technological feasibility, CARB is to consider emissions from SOREs in the state, a timeline for zero-emission SORE development, increased electricity demand from charging zero-emission SORE, cases for both commercial and residential users of SOREs, and expected availability of zero-emission generators and emergency response equipment. In addition, CARB is to identify and make available funding for rebates or incentive funding. CARB adopted engine exhaust emission regulations for SORE in compliance with AB 1346 requiring most new SORE to be zero emissions by 2024.

Portable Equipment Registration Program

The Statewide Portable Equipment Registration Program (PERP) establishes a system to uniformly regulate portable engines and portable engine–driven equipment units. After being registered in this program, engines and equipment units may operate throughout the state without the need to obtain permits from individual air districts. Owners or operators of portable engines and certain types of equipment can voluntarily register their units under this program. Operation of registered portable engines may still be subject to certain district requirements for reporting and notification. Engines with less than 50 brake hp are exempt from this program.

California Control Measures for Airborne Toxic Air Contaminants

CARB identifies substances as TACs as defined in Health and Safety Code Section 39655 and listed in Title 17, Section 93000 of the CCR, "Substances Identified as Toxic Air Contaminants." Airborne Toxic Control Measures (ATCM), including the following relevant measures, are implemented to address sources of TACs:

- ATCM for DPM from Portable Engines Rated at 50 hp and Greater
- ATCM to Limit Diesel-Fueled Commercial Motor Vehicle Idling
- ATCM to Reduce Particulate Emissions from Diesel-Fueled Engines Standards for Non-vehicular Diesel Fuel
- ATCM for Stationary Compression Ignition Engines
- Asbestos ATCM for Construction, Grading, Quarrying, and Surface Mining Operations
- Asbestos ATCM for Surfacing Applications

In addition to ATCMs, TACs are controlled under several regulations in California, including the Tanner Air Toxics Act, Air Toxics Hot Spots Information Act, and AB 2588: Air Toxics "Hot Spots" Information and Assessment Act. In addition, Proposition 65 (the Safe Water and Toxic Enforcement Act of 1996) requires California to publish a list of chemicals known to cause cancer or birth defects or other reproductive harm. Proposition 65 requires businesses to notify Californians about substantial amounts of chemicals in the products they purchase or that are released into the environment.

ZEV Executive Orders

In March 2012, then-Governor Brown issued EO B-16-12 establishing a goal of 1.5 million ZEVs on California roads by 2025.In addition to the ZEV goal, the executive order stipulated that by 2015 all major cities in California will have adequate infrastructure and be “zero-emission vehicle ready”; that by 2020 the State will have established adequate infrastructure to support 1 million ZEVs; and that by 2050, virtually all personal transportation in the state will be based on ZEVs, and GHG emissions from the transportation sector will be reduced by 80 percent below 1990 levels.

On January 26, 2018, then-Governor Brown issued EO B-48-18 establishing a goal of 5 million ZEVs on California roads by 2030 and spurred the installation and construction of 250,000 plug-in electric vehicle chargers, including 10,000 direct current fast chargers, and 200 hydrogen refueling stations by 2025.

In September 2020, Governor Newsom signed EO N-79-20, which sets a new State goal that 100 percent of in-state sales of new passenger cars and trucks will be zero-emission by 2035; that 100 percent of medium- and heavy-duty vehicles in the state be zero-emission by 2045 for all operations, where feasible, and by 2035 for drayage trucks; and that 100 percent of off-road vehicles and equipment will be zero emission by 2035, where feasible. This order calls upon state agencies, including CARB, the CEC, the CPUC, the Department of Finance, and others to develop and propose regulations and strategies to achieve these goals.

3.3.2.3 Regional Laws, Regulations, and Policies

BAAQMD 2022 CEQA Guidelines

In December 1999, the BAAQMD adopted its initial *CEQA Guidelines – Assessing the Air Quality Impacts of Projects and Plans* (BAAQMD *CEQA Guidelines*), as a guidance document to provide lead government agencies, consultants, and project proponents with uniform procedures for assessing air quality impacts and preparing the air quality sections of environmental documents for projects subject to CEQA. The BAAQMD *CEQA Guidelines* is an advisory document and local jurisdictions are not required to use the methodology outlined therein. The document describes the criteria that the BAAQMD uses when reviewing and commenting on the adequacy of environmental documents. It recommends thresholds for use in determining whether projects would have significant adverse environmental impacts, identifies methodologies for predicting project emissions and impacts, and identifies measures that can be used to avoid or reduce air quality impacts.

The BAAQMD updated quantitative thresholds of significance for its CEQA air quality guidelines in 2010 and published its latest version of its BAAQMD *CEQA Guidelines* in April 2023 (BAAQMD 2023a). The BAAQMD 2022 *CEQA Guidelines* provide BAAQMD-recommended procedures for evaluating potential air quality impacts during the environmental review process consistent with CEQA requirements.

The guidelines specify recommended thresholds of significance for construction and operational criteria air pollutants and precursor emissions, GHG emissions, and risks and hazards associated with TACs from an individual project and cumulative impact, discussed in Section 3.3.3, *Methodology and Approach to Impact Analysis*.

BAAQMD 2017 Clean Air Plan

The BAAQMD has developed the *Spare the Air-Cool the Climate: A Blueprint for Clean Air and Climate Protection in the Bay Area Final 2017 Clean Air Plan* (2017 Clean Air Plan), which details planned efforts to improve Bay Area air quality, including reducing PM and TAC emissions, and protecting public health. In addition, the 2017 Clean Air Plan simultaneously updates the 2010 Clean Air Plan, which is the most recent ozone plan for the Bay Area, to comply with state air quality planning requirements and reduce ozone precursors (BAAQMD 2017c ~~2017b~~). The 2017 Clean Air Plan contains a control strategy that includes 85 individual control measures to reduce emissions of criteria air pollutants and GHGs from the full range of emission sources. The measures include stationary (industrial) sources, transportation, energy, buildings, agriculture, natural and working lands, waste management, and water (BAAQMD 2017c ~~2017b~~).

BAAQMD Particulate Matter Plan

On January 9, 2013, the USEPA issued a final rule to determine that the SFBAAB attains the 24-hour $PM_{2.5}$ standard (78 Federal Register 1760; January 9, 2013). This USEPA rule suspends key State Implementation Plan (SIP) requirements as long as monitoring data continue to show that the SFBAAB attains the standard. Despite this USEPA action, the SFBAAB will continue to be designated as “nonattainment” for the national 24-hour $PM_{2.5}$ standard until the BAAQMD submits a “redesignation request” and a “maintenance plan” to USEPA, and USEPA approves the proposed redesignation.

For PM emissions, the BAAQMD has developed various rules, programs, and measures to identify and control sources of PM, including general PM emission requirements, a Winter Spare the Air program, and control measures identified in the 2017 Clean Air Plan (BAAQMD 2017c ~~2017b~~). The 2017 Clean Air Plan includes a variety of control measures to reduce PM emissions, including, but not limited to, expanding the BAAQMD’s fugitive dust visible emissions limits to a wider array of sources, reducing DPM emissions from emergency generators, and developing a rule to prevent mud/dirt track-out from construction and other sites (BAAQMD 2017c ~~2017b~~).

BAAQMD 2005 Ozone Strategy

For ozone precursor management, the BAAQMD has identified measures in the 2017 Clean Air Plan and the Bay Area 2005 Ozone Strategy that include stationary-source control measures to be implemented through BAAQMD regulations; mobile-source control measures to be implemented through incentive programs and other activities; and transportation control measures to be implemented through transportation programs in cooperation with the Metropolitan Transportation Commission, local governments, transit agencies, and other agencies (BAAQMD 2006).

BAAQMD Rules

The BAAQMD supports incentive programs to reduce criteria pollutant emissions, TACs, and odors within the district and has established rules and permitting requirements. The Project may be subject to the following BAAQMD rules:

Regulation 2 (Permits): This regulation outlines the air permitting program, including exemptions and sources needing permitting.

Regulation 2, Rule 1 (New Source Permits): This rule applies to all new or modified sources requiring a permit. This rule requires the analysis of new or modified sources to ensure that if emissions do exceed specific applicable thresholds that "Best Available Control Technology" is installed to limit the emissions to the greatest extent possible.

Regulation 2, Rule 2 (New Source Review): This rule outlines permitting process for new sources.

Regulation 2, Rule 5 (New Source Review of TACs): This rule outlines guidance for evaluating TAC emissions and their potential health threats.

Regulation 6, Rule 1 (Particulate Matter Requirements): This rule limits the quantity of PM in the atmosphere through the establishment of limitations on emission rates, emissions concentrations, visible emissions, and opacity.

Regulation 6, Rule 6 (Prohibition of Trackout): This rule limits the quantity of PM in the atmosphere through control of trackout of solid materials onto paved public roads outside the boundaries of large construction sites.

Regulation 7 (Odorous Substances): This regulation places general limitations on odorous substances and specific emission limitations on certain odorous compounds.

Regulation 8, Rule 3 (Architectural Coasting): This rule limits the quantity of volatile organic compounds that can supplied, sold, applied, and manufactured within the BAAQMD region.

Regulation 8, Rule 15 (Emulsified and Liquid Asphalts): This rule limits the reactive organic gases content of asphalt available for use during construction through regulating the sale and use of asphalt and limits the ROG content in asphalt.

Regulation 9, Rule 2 (Hydrogen Sulfide): The rule limits ground level concentrations of hydrogen sulfide.

Regulation 9, Rule 8 (Nitrogen Oxides and Carbon Monoxide from Stationary Internal Combustion Engines): This rule limits the emissions of NO_x and CO from stationary internal combustion engines with an output rated by the manufacturer at more than 50 brake horsepower. In addition, Section 9-8-330 states that an emergency standby engine cannot be operated for more than 50 hours in a calendar year for testing and maintenance purposes.

Regulation 11, Rule 14 (Asbestos-Containing Serpentine): The purpose of this rule is to control emissions of asbestos from unpaved road surfaces and other surfacing operations. This rule limits the use of serpentine material with >5% asbestos content for covering roads or paths.

3.3.2.4 Local Laws, Regulations, and Policies

Santa Clara County General Plan

The Santa Clara County General Plan Health Element (2015) and the General Plan (1994) contain the following policies relevant to air quality:

Policy HE-G.1: Air quality environmental review. Continue to utilize and comply with the Air District's project- and plan-level thresholds of significance for air pollutants and GHG emissions.

Policy HE-G.2: Coordination with regional agencies. Coordinate with the Air District to promote and implement stationary and area source emission measures.

Policy HE-G.3: Fleet upgrades. Promote Air District mobile source measures to reduce emissions by accelerating the replacement of older, dirtier vehicles and equipment, and by expanding the use of zero emission and plug-in vehicles.

Policy HE-G.4: Off-road sources. Encourage mobile source emission reduction from off-road equipment such as construction, farming, lawn and garden, and recreational vehicles by retrofitting, retiring, and replacing equipment and by using alternate fuel vehicles.

Policy HE-G.7: Sensitive receptor uses. Promote measures to protect sensitive receptor uses, such as residential areas, schools, day care centers, recreational playfields and trails, and medical facilities by locating uses away from major roadways and stationary area sources of pollution, where possible, or incorporating feasible, effective mitigation measures.

Policy C-HS 1: Ambient air quality for Santa Clara County should comply with standards set by state and federal law.

Policy C-HS 12: Measures to reduce particulate matter pollution originating from quarrying, road, and building construction, industrial processes, unpaved parking lots, and other sources should be encouraged.

Policy C-HS(i) 1: Reductions in vehicular exhaust emissions also contribute to reductions in levels of suspended particulate matter.

Policy C-HS(i) 2: Low-cost techniques such as washing the tires of construction vehicles to remove soil before they leave a site prevents soils from being deposited on roadways, where it may be "re-entrained" by other traffic and produce high levels of the particulates.

City of Morgan Hill General Plan

The Natural Resources and Environment chapter of the City of Morgan Hill General Plan (2017 ~~2016~~) contains the following goals, policies, and actions relevant to air quality:

Goal NRE-10: Reduced air pollution emissions.

Policy NRE-10.1: Regional and Subregional Cooperation. Cooperate with regional agencies in developing and implementing air quality management plans. Support subregional coordination with other cities, counties, and agencies in the Santa Clara Valley and adjacent areas to address land use, jobs/housing balance, and transportation planning issues as a means of improving air quality.

Goal NRE-11: Minimized exposure of people to toxic air contaminants such as ozone, carbon monoxide, lead, and particulate matter.

Policy NRE-11.1: TACs and Proposed Sensitive Uses. Require modeling for sensitive land uses, such as residential development, proposed near sources of pollution such as freeways, and industrial uses. Require new residential development and projects categorized as sensitive receptors to incorporate effective mitigation measures into project designs or be located adequate distances from sources of TACs to avoid significant risk to health and safety.

Policy NRE-11.2: TACs and Existing Sensitive Uses. Encourage the installation of appropriate air filtration mechanisms at existing schools, residences, and other sensitive receptors adversely affected by existing or proposed pollution sources.

Policy NRE-11.3: Health Risk Assessments. For proposed development that emits toxic air contaminants, require project proponents to prepare health risk assessments in accordance with BAAQMD procedures as part of environmental review and implement effective mitigation measures to reduce potential health risks to less-than-significant levels. Alternatively, require these projects to be located an adequate distance from residences and other sensitive receptors to avoid health risks. Consult with the BAAQMD to identify stationary and mobile toxic air contaminant sources and determine the need for and requirements of a health risk assessment for proposed developments.

Policy NRE-11.4: Truck Routes. For development projects generating significant heavy-duty truck traffic, designate truck routes that minimize exposure of sensitive receptors to toxic air contaminants and particulate matter.

Policy NRE-11.5: Truck Idling. For development projects generating significant truck traffic, require signage to remind drivers that the State truck idling law limits truck idling to five (5) minutes.

Policy NRE-11.6 Vegetation Buffers. Encourage the use of pollution-absorbing trees and vegetation in buffer areas between substantial sources of toxic air contaminants and sensitive receptors.

Goal NRE-12: Minimized air pollutant emissions from demolition and construction activities.

Policy NRE-12.1: Best Practices. Requirement that development projects implement best management practices to reduce air pollutant emissions associated with construction and operation of the project.

Policy NRE-12.2: Conditions of Approvals. Include dust, particulate matter, and construction equipment exhaust control measures as conditions of approval for subdivision maps, site development and planned development permits, grading permits, and demolition permits. At a minimum, conditions shall conform to construction mitigation measures recommended in the current BAAQMD CEQA Guidelines.

Policy NRE-12.3: Control Measures. Require construction and demolition projects that have the potential to disturb asbestos (from soil or building material) to comply with all the requirements of the California Air Resource Board’s ATCMs for Construction, Grading, Quarrying, and Surface Mining Operations.

Policy NRE-12.4: Grading. Require subdivision designs and site planning to minimize grading and use landform grading in hillside areas.

Action NRE-12.A: Standard Measures for Demolition and Grading. Adopt and periodically update dust, particulate matter, and exhaust control standard measures for demolition, grading, and construction activities to include on project plans mitigation measures as conditions of approval-based BAAQMD CEQA Guidelines. Include measures to prevent silt loading on roadways that generate particulate matter air pollution by prohibiting unpaved or unprotected access to public roadways from construction sites.

Action NRE-12.B: Grading Ordinance. Revise the grading ordinance and condition grading permits to require that graded areas be stabilized from the completion of grading to commencement and construction.

Goal NRE-14: Minimum exposure of residents to objectionable odors.

Policy NRE-14.1: New Odor Sources. For new, expanded, or modified facilities that are potential sources of objectionable odors, require an analysis of possible odor impacts and the provision of odor minimization and control measures as mitigation.

Policy NRE-14.2: Odors and Proposed Sensitive Uses. Require new residential development projects and projects categorized as sensitive receptors to be located an adequate distance from facilities that are existing or potential sources of odor. Determine the adequate separation distance based on the type, size, and operations of the facility.

City of Morgan Hill Zoning Code

Condition 18.76.100 of the City of Morgan Hill's Zoning Code (2018) prohibits objectionable odors that are perceptible by a reasonable person at the lot line of a site. However, odors from temporary construction, demolition, and vehicles that enter and leave the site (e.g., construction equipment, trains, trucks, etc.) are exempt from this standard.

Envision San José 2040 General Plan

The Envision San José 2040 General Plan (2023 ~~2011~~) contains the following policies/actions relevant to air quality:

Goal MS-10: Minimize air pollutant emissions from new and existing development.

Policy MS-10.1: Assess projected air emissions from new development in conformance with BAAQMD CEQA Guidelines and relative to state and federal standards. Identify and implement feasible air emission reduction measures.

Policy MS-10.2: Consider the cumulative air quality impacts from proposed developments for proposed land use designation changes and new development, consistent with the region's Clean Air Plan and State law.

Policy MS-10.8: Minimize vegetation removal required for fire prevention. Require alternatives to discing, such as mowing, to the extent feasible. Where vegetation removal is required for property maintenance purposes, encourage alternatives that limit the exposure of bare soil.

Policy MS-10.9: Foster educational programs about air pollution problems and solutions.

Action MS-10.14: Review and evaluate the effectiveness of site design measures, transit incentives, and new transportation technologies, and encourage those that most successfully reduce air pollutant emissions.

Goal MS-11: Minimize exposure of people to air pollution and toxic air contaminants such as ozone, carbon monoxide, lead, and particulate matter.

Policy MS-11.1: Require completion of air quality modeling for sensitive land uses such as new residential developments that are located near sources of pollution such as freeways and industrial uses. Require new residential development projects and projects categorized as sensitive receptors to incorporate effective mitigation into project designs or be located an adequate distance from sources of TACs to avoid significant risks to health and safety.

Policy MS-11.2: For projects that emit toxic air contaminants, require project proponents to prepare health risk assessments in accordance with BAAQMD-recommended procedures as part of environmental review and employ effective mitigation to reduce possible health risks to a less than significant level. Alternatively, require new projects (such as, but not limited to, industrial, manufacturing, and processing facilities) that are sources of TACs to be located an adequate distance from residential areas and other sensitive receptors.

Policy MS-11.3: Review projects generating significant heavy-duty truck traffic to designate truck routes that minimize exposure of sensitive receptors to TACs and particulate matter.

Policy MS-11.4: Encourage the installation of appropriate air filtration at existing schools, residences, and other sensitive receptor uses adversely affected by pollution sources.

Policy MS-11.5: Encourage the use of pollution absorbing trees and vegetation in buffer areas between substantial sources of TACs and sensitive land uses.

Action MS-11.7: Consult with BAAQMD to identify stationary and mobile TAC sources and determine the need for and requirements of a health risk assessment for proposed developments.

Action MS-11.8: For new projects that generate truck traffic, require signage which reminds drivers that the State truck idling law limits truck idling to five minutes.

Goal MS-12: Minimize and avoid exposure of residents to objectionable odors.

Policy MS-12.1: For new, expanded, or modified facilities that are potential sources of objectionable odors (such as landfills, green waste and resource recovery facilities, wastewater treatment facilities, asphalt batch plants, and food processors), the City requires an analysis of possible odor impacts and the provision of odor minimization and control measures as mitigation.

Policy MS-12.2: Require new residential development projects and projects categorized as sensitive receptors to be located an adequate distance from facilities that are existing and potential sources of odor. An adequate separation distance will be determined based upon the type, size, and operations of the facility.

Goal MS-13: Minimize air pollutant emissions during demolition and construction activities.

Policy MS-13.1: Include dust, particulate matter, and construction equipment exhaust control measures as conditions of approval for subdivision maps, site development and planned development permits, grading permits, and demolition permits. At minimum, conditions shall conform to construction mitigation measures recommended in the current BAAQMD CEQA Guidelines for the relevant project size and type.

Policy MS-13.2: Construction and/or demolition projects that have the potential to disturb asbestos (from soil or building material) shall comply with all the requirements of the California Air Resources Board's ATCMs for Construction, Grading, Quarrying, and Surface Mining Operations.

Policy MS-13.3: Require subdivision designs and site planning to minimize grading and use landform grading in hillside areas.

Policy EC-4.6: Evaluate development proposed in areas with soils containing naturally occurring asbestos (i.e., serpentinite) that would require ground disturbance and/or development of new residential or other sensitive uses, for risks to people from airborne asbestos particles during construction and post-construction periods. Hazards shall be assessed, at minimum, using guidelines and regulations of the BAAQMD and the CARB.

Policy EC-7.7: Determine for any development or redevelopment site that is within 1,000 feet of a known, suspected, or likely geographic ultramafic rock unit (as identified in maps developed by the Department of Conservation – Division of Mines and Geology) or any other known or suspected locations of serpentine or naturally occurring asbestos, if naturally occurring asbestos exists and, if so, comply with the BAAQMD's Asbestos ATCM requirements.

3.3.3 Methodology and Approach to Impact Analysis

This impact analysis considers whether implementation of the Project would result in significant impacts related to air quality. This section includes an evaluation of the criteria air pollutants and TAC emissions generated by the Project and if the Project would conflict with any applicable plan or policy for air quality. This section also includes a health risk assessment (HRA) to evaluate the health effects of TACs and $PM_{2.5}$ during Project construction. The analysis evaluates the criteria air pollutants and TAC emissions that would occur as a result of the following activities:

- Seismic Retrofit Construction
- Conservation Measure Construction
- Construction Monitoring
- Post-Construction Anderson Dam Facilities Operations and Maintenance
- Post-Construction Conservation Measures Operations and Maintenance
- Post-Construction FAHCE Adaptive Management

3.3.3.1 Seismic Retrofit Construction

As described in Section 3.0, *Introduction*, the baseline for evaluating Seismic Retrofit construction effects is the existing conditions at the time of EIR preparation modified by the FOCP implementation (referred to as the existing conditions baseline). Existing baseline operations for the Project reflect a seismically restricted capacity (e.g., maintenance of the reservoir at deadpool), and flow releases and maintenance activities projected to occur following completion of the FOCP, presently under construction. Similarly, the construction baseline assumes completion of facility upgrades and physical changes associated with the FOCP.

Criteria Pollutant Emissions

The CEQA Air Quality, Greenhouse Gas and Health Risk Assessment Technical Report (Ramboll 2024) (Appendix E), which supports the air quality assessment in this section, primarily used the methodology from the California Emissions Estimator Model (CalEEMod) version 2022.1 to quantify the criteria pollutant emissions for the Project. CalEEMod incorporates numerous default assumptions and CARB emission factors for on-road and off-road vehicles. The emission factors for off-road equipment and mobile sources were obtained from the latest versions of CARB's OFFROAD and EMission FACtor (EMFAC) models, respectively. Emissions calculations associated with off-road construction equipment were based on the construction schedule and the type, size, fuel type, tier level, hours of operation and utilization factor for each piece of equipment. For diesel-powered off-road construction equipment, methodologies consistent with CalEEMod were used to estimate emissions. Where Project-specific equipment information was not available, CalEEMod default hp was used. Load factors for each piece of equipment were based on default factors from CalEEMod. On-site boat emissions were estimated using emission factors and methodology from CARB's Pleasure Craft Model Database, matched to their respective gasoline-fueled boat classifications. Blasting-related emissions were estimated using methods from the Mojave Desert Air Quality Management District (MDAQMD) Emissions Inventory Guidance for Mineral Handling and Processing Industries (MDAQMD 2013) and USEPA's AP-42, and San Joaquin Valley Air Pollution Control District's guidance for hexavalent chromium. Emissions calculations associated with blasting activities were based on the number of blast holes drilled, type of explosives, and amounts of material shifted by blasting, as provided by Valley Water. Emissions assumed one complete blast occurs in 1 hour of activity. Emissions from on-road construction trips for workers, vendors, and haul trucks were estimated using emissions factors from EMFAC2021. EMFAC2021 incorporates the Pavley Clean Car Standards and the Advanced Clean Cars program.

Project construction activities would be completed using a combination of off-road and portable construction equipment. It was assumed that all construction off-road equipment is diesel powered except for those specified as electric or gasoline powered. Specific construction equipment assumptions for each phase and construction trip assumptions for workers, vendors, and haul trucks are provided in Appendix E.

Seismic retrofit construction is anticipated to span a 7-year period. The specific construction phasing schedule is provided in Appendix E. Annual emissions were averaged over the number of work days in each construction year to give average daily emissions in pounds per day. Average daily emissions were calculated for each phase of construction, then summed for all phases that occur concurrently.

Mitigated emissions account for the implementation of **Mitigation Measure AQ-1** and **Mitigation Measure AQ-2**. **Mitigation Measure AQ-1** would require the use of Tier 4 engines for off-road equipment and 2010 or newer on-road heavy duty diesel trucks and boat engines. **Mitigation Measure AQ-2** calls for the use of blasting wind screens during construction blasting activities.

Application of BAAQMD-Recommended Mitigation and ATCMs

BAAQMD recommends the implementation of Basic Best Management Practices for Construction-Related Fugivite Dust Emissions (see Appendix A, BMP-AQ-1[2]) as mitigation for fugitive dust from construction. BAAQMD considers the impact of construction-related fugitive dust emissions to be less than significant if all the Basic Best Management Practices (i.e., measures from BMP-AQ-1) are implemented.

In addition, all projects must implement any applicable ATCMs. This includes the ATCM for DPM from portable engines; ATCM to limit diesel-fueled commercial motor vehicle idling; ATCM to reduce particulate emissions from diesel-fueled engines (for non-vehicular diesel fuel); ATCM for stationary compression ignition engines; asbestos ATCM for surfacing applications, and asbestos ATCM for construction, grading, and blasting. For more details on NOA, see Section 3.10, *Hazards and Hazardous Materials*.

Quantification methodologies for emission reductions from fugitive dust mitigation measures is not available for all types of mitigation listed in BMP-AQ-1 and **Table 3.3-4**; thus, no quantified reductions in fugitive dust emissions are shown. Instead, these measures represent best practices for controlling fugitive dust and reducing emissions to a less-than-significant level. In addition to the fugitive dust BMPs, the Project would require a BAAQMD-approved Dust Mitigation Plan pursuant to the California Asbestos ATCM for Construction, Grading, Quarrying, and Surface Mining Operations (CCR Title 17, Section 93105). The Dust Mitigation Plan would include all applicable dust control BMPs listed in BMP-AQ-1, may include other asbestos-specific dust control requirements, and may also require soil and ambient air sampling for asbestos fibers.

Health Risk Assessment

In order to evaluate the impact of exposing sensitive receptors to TACs, an HRA was conducted to evaluate the potential human health effects of onsite off-road construction equipment DPM emissions, total organic gases (TOG) from gasoline combustion and TACS anticipated to be in PM from blasting~~, as detailed in Section 3.3.1.5 above~~. The HRA evaluated excess lifetime cancer risk, noncancer chronic HI, and primary $PM_{2.5}$ concentration for offsite sensitive receptor exposure to emissions from Project construction. Additional details of the HRA not contained in this summary are found in Appendix E. The HRA does not include an assessment of asbestos exposure as this is controlled to protect human health with implementation of the ATCM and required measures under the Dust Mitigation Plan, and no further analysis is typically required

2 Note: As detailed in Section 3.3.3.7, *Applicable Best Management Practices and BAAQMD Measures*, BMP AQ-1 includes a requirement that vehicles on unpaved roads observe a 15 mile per hour speed limit. To make this BMP feasible for the Project, this BMP would be modified to allow haul trucks to travel up to 25 miles per hour on unpaved roads, except in areas with naturally occurring asbestos where the 15 miles per hour limit would still apply.

beyond discussing compliance with the regulations (BAAQMD 2017a ~~2017c~~). The purpose of the ATCM and Dust Mitigation Plan is to reduce public exposure to fugitive dust, which includes NOA from construction activities that emit or re-suspend dust which may contain asbestos. Section 3.10, *Hazards and Hazardous Material*, addresses potential asbestos-related impacts in greater detail.

The exhaust emissions from all onsite off-road equipment were estimated using methods consistent with CalEEMod following the same assumptions as the criteria pollutant mass emissions. It was assumed that all exhaust PM_{10} from off-road equipment was equal to DPM. USEPA's recommended air dispersion model, AERMOD (version 22112), was used to estimate the concentration of DPM at various sensitive receptors located near the Project construction areas. Standard guidance from the OEHHA and BAAQMD was used to estimate exposure, dose, and health impacts, including cancer and chronic noncancer health effects. This includes using the latest OEHHA recommended breathing rates and age-specific factors (ASF) (OEHHA 2015) for the various sensitive receptor populations. Sensitive receptor populations that were quantified include resident adult, resident child, day care child, preschool child, and juvenile detention residents. The California Environmental Protection Agency-approved (CalEPA) toxicity values for DPM were used to evaluate health impacts from construction and operational diesel fueled sources (CalEPA 2022).

Health effects from exhaust and evaporation from gasoline combustion were based on specific TAC emissions. Emissions of TOG from gasoline-fueled vehicles and boats were speciated using organic chemical profiles from BAAQMD (BAAQMD 2012).[3] The organic profile used for gasoline trucks and boats can be found in Appendix E. The CalEPA-approved toxicity values for each TAC were used to evaluate health impacts from operational gasoline fueled sources (CalEPA 2022).

The HRA provides a characterization of the excess cancer risks that could occur due to exposure to DPM and TACs associated with Project construction. The excess cancer risk is generally multiplied by 1 million to report the excess cancer risk that would be expected to occur based on the exposure to DPM in a population of 1 million people.

Besides cancer risk, DPM, gasoline exhaust TACs and other TACs (e.g., heavy metals and silica) associated with the Project can also have acute and chronic non-cancer health effects. To determine the significance of the acute and chronic non-cancer health impact, the ambient air concentration is divided by the Reference Exposure Level to provide the hazard quotient. If several TACs are present, the individual hazard quotients are summed to reach an overall hazard index (HI). The concentration of $PM_{2.5}$ at locations near the Project area was also quantified using the dispersion modeling methods described above.

In addition to evaluating Project impacts, cumulative impacts were evaluated against the BAAQMD's cumulative risk thresholds. Impacts from construction- and operation-related emissions from nearby existing or reasonably foreseeable projects, roadways with over 10,000 vehicles per day, and railways (within 1,000 feet of the construction site) were evaluated. If specific health impacts from these reasonably foreseeable cumulative projects are known or are

[3] Speciation profile is from BAAQMD's Recommended Methods for Screening and Modeling Local Risks and Hazards (BAAQMD 2012), Table 14, Toxic Speciation of TOG due to Tailpipe Emissions, and Table 15, Toxic Speciation of TOG due to Evaporative Losses.

expected to have an impact on sensitive receptors evaluated in the HRA, the impacts of those projects were added to the maximum exposed individual sensitive receptor.

Throughout FOCP construction certain trails and public access to Anderson Dam and Reservoir were closed for public safety. This would continue throughout the Seismic Retrofit construction portion of the Project. Trails in Rosendin Park would also be fully closed for 3 to 4 months during the initial blasting phase of the Seismic Retrofit Components construction which would occur sometime during Year 4, 5, or 6 of Project construction, and be partially closed throughout the duration of blasting in Years 4, 5, and/or 6 (with the nearest open trails over 900 feet from the blasting area, though typically much further). Aside from the trail closures within the Project boundaries of the BHBA, there would be no planned closures of the Rosendin Park Area before Year 4 or after Year 6 of Project construction. Since recreational receptors are unlikely to be present and exposed to air toxics from Project construction for an extended duration, health risk impacts on Rosendin Park receptors are expected to be low and were not quantified in this analysis.

Odors

Odor impacts were assessed based on the source of anticipated odors and whether those sources would generate objectionable odors. Screening distances for potential odor impacts are discussed below in Section 3.3.3.8, *Thresholds of Significance*.

3.3.3.2 Conservation Measures Construction

As described in Section 3.0, *Introduction*, the baseline for evaluating Conservation Measure construction effects is the existing conditions at the time of EIR preparation modified by the FOCP implementation (i.e., existing conditions baseline). Conservation Measures involving construction activities with a potential to result in a substantial amount of air pollutant emissions ~~adversely affect air quality~~ that are evaluated in the impact analysis include:

- Ogier Ponds CM
- ~~North Channel Extension~~
- Sediment Augmentation Program
- Phase 2 Coyote Percolation Dam CM

The air quality impacts from the construction of the Conservation Measure components were analyzed using the same methodologies as the Seismic Retrofit construction. Construction activities associated with the Ogier Ponds CM would occur from Year 6 through Year 8 ~~Year 9~~; Sediment Augmentation Program would occur in Year 8[4] ~~from Year 2 through Year 15~~; and Phase 2 Coyote Percolation Dam CM would occur during Year 1 and Year 2 ~~from Year 4 through Year 5~~. Maintenance of the North Channel Reach and the Live Oak Restoration Reach would involve only minor and intermittent maintenance activities (e.g., vegetation management, replacement planting, etc.) and would not result in any substantial amount of air pollutant emissions; therefore, these Conservation Measures are not discussed further in this section. ~~The~~

[4] Air pollutant emissions were only quantified for the initial placement of gravel, assumed to occur in Year 8. While emissions associated with future gravel augmentation are assumed to be minor, their scale, timing, and duration are speculative and were not quantified.

~~North Channel Extension Conservation Measure would occur for 2 months in Year 1 and Year 7. Due to the short duration, small number of equipment and workers required, and lack of high-emissions activities, impacts from the North Channel Extension are anticipated to be small in comparison to the impacts of the Seismic Retrofit and other Conservation Measures. Thus, a quantitative analysis of this Conservation Measure was not performed.~~ A detailed construction schedule for the Conservation Measures, specific construction equipment assumptions for the Conservation Measures, and construction trip assumptions for the Conservation Measures for workers, vendors, and haul trucks are provided in Appendix E.

3.3.3.3 Construction Monitoring

Construction monitoring activities are not included in the impact analysis, as monitoring would involve data and information collection and assessment and would not result in any substantial amount of air pollutant emissions. Thus, construction monitoring is not discussed further in this section.

3.3.3.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

Operation of the Anderson Dam following construction of the Project would involve implementation of the FAHCE rule curves and pulse flows, which would not result in additional air pollutant emissions compared to the existing conditions baseline. In addition, a diesel generator is proposed at the new outlet works, which would replace an existing diesel generator in the same general area, resulting in no net increase of criteria air pollutants or TACs above baseline conditions. Additionally, as described in Chapter 2, *Project Description*, Valley Water would maintain the newly retrofitted Anderson Dam and Reservoir per Valley Water's existing DMP. Maintenance of Anderson Dam facilities was previously evaluated in the Final DMP EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). No new long-term operational sources of emissions would be generated by the Project; therefore, this EIR evaluates construction emissions but does not evaluate future Anderson Dam maintenance and operations activities.

3.3.3.5 Post-Construction Conservation Measures Operations and Maintenance

Similar to the operation of the Anderson Dam, post-construction operations and maintenance of the Conservation Measures components would involve minimal activities generating air pollutant emissions. Additionally, as described in Chapter 2, *Project Description*, Valley Water would maintain Coyote Percolation Dam per Valley Water's existing DMP. Maintenance of Coyote Percolation Dam facilities were previously evaluated in the Final DMP EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). No new long-term operational sources generating air pollutant emissions would be added by the post-construction Conservation Measures operations and maintenance. Therefore, operations and maintenance of the Conservation Measures components would not result in significant impacts to air pollutant emissions, and these Conservation Measures operations and maintenance impacts are not discussed further in this section.

3.3.3.6 Post-Construction Project and FAHCE Adaptive Management

The Project and FAHCE AMP would guide post-construction adaptive management of project flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are not evaluated in the impact analysis, because they would result in only minor air pollutant emissions.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. Therefore, impacts of these operational adaptive management actions are not evaluated in the impact analysis, because they would result in only minor air pollutant emissions.

3.3.3.7 Applicable Best Management Practices and VHP Conditions ~~BAAQMD Measures~~

The following Valley Water BMPs would serve to minimize impacts on air quality from the Project (refer to Chapter 2, *Project Description*, for the full text of the BMPs):

- **AQ-1:** Use Dust Control Measures
- **AQ-2:** Avoid Stockpiling Odorous Materials

Additionally, the following BAAQMD-recommended measures ~~mitigation~~ and airborne toxic control measures (ATCMs) would be implemented**.** BAAQMD recommends the implementation of Basic Best Management Practices for Construction-Related Fugitive Dust Emissions, because it is difficult to quantify all types of fugitive dust emissions and reductions of those emissions attributable to mitigation measures. These measures overlap with Valley Water BMP AQ-1. BAAQMD considers the impact of construction-related fugitive dust emissions to be less than significant if all the basic best management practices for construction are implemented. BAAQMD strongly recommends implementing all feasible fugitive dust management practices (e.g., enhanced construction BMPs), especially when construction activities are near sensitive receptors. Due to the unique and complex nature of Seismic Retrofit Construction, one minor variance from the BAAQMD BMPs related to vehicle speeds on unpaved roads is necessary in certain situations and areas to make it feasible for the Project, as shown in the footnote below.

- Basic Best Management Practices for Construction-Related Fugitive Dust Emissions (BAAQMD 2023a)
  1. All exposed surfaces (e.g., parking areas, staging areas, soil piles, graded areas, and unpaved access roads) shall be watered two times per day.
  2. All haul trucks transporting soil, sand, or other loose material offsite shall be covered.
  3. All visible mud or dirt track-out onto adjacent public roads shall be removed using wet power vacuum street sweepers at least once per day. The use of dry power sweeping is prohibited.
  4. All vehicle speeds on unpaved roads not surfaced with aggregate base shall be limited to 15 miles per hour.[5]
  5. All roadways, driveways, and sidewalks to be paved shall be completed as soon as possible. Building pads shall be laid as soon as possible after grading unless seeding or soil binders are used.
  6. All excavation, grading, and/or demolition activities shall be suspended when average wind speeds exceed 20 miles per hour for more than 30 minutes.
  7. All trucks and equipment, including their tires, shall be washed prior to leaving the site.
  8. Unpaved roads providing access to sites located 100 feet or further from a paved road shall be treated with a 6- to 12-inch layer of compacted wood chips, mulch, or gravel.
  9. Publicly visible signs shall be posted with the telephone number and person to contact at the Lead Agency regarding dust complaints. This person shall respond and take corrective action within 48 hours. The Air District's General Air Pollution Complaints phone number shall also be visible to ensure compliance with applicable regulations.

As noted above, all projects must implement any applicable ATCMs. This includes the ATCM for DPM from portable engines; ATCM to limit diesel-fueled commercial motor vehicle idling; ATCM to reduce particulate emissions from diesel-fueled engines (for non-vehicular diesel fuel); ATCM for stationary compression ignition engines; asbestos ATCM for surfacing applications, and asbestos ATCM for construction, grading, quarrying, and surface mining operations (discussed in the *Hazards and Hazardous Materials* section). In addition, all projects must comply with BAAQMD Rule 6-1, which limits fugitive particulate emissions, and Rule 6-6, which limits trackout of solid materials onto paved public roads outside the boundaries of large construction sites.

No VHP conditions are applicable to air quality.

[5] The 15 miles per hour speed limit would apply to all vehicles and equipment only in areas containing naturally occurring asbestos. Outside of these areas, a 25 mile per hour speed limit would be observed for haul trucks on unpaved roads (light duty pick-up trucks would observe the 15 mile per hour limit), such as the in-reservoir access roads to Stockpile Areas K and L. Limiting haul truck speeds to 15 miles per hour on all unpaved access roads would not be feasible to construct the Project interim dam to its full height, as the interim dam at the proposed height could not be reconstructed in a single work season.

3.3.3.8 Thresholds of Significance

Significance Criteria

For the purposes of this EIR and pursuant to Appendix G of the *CEQA Guidelines*, the Project would result in a significant impact on air quality if it would:

- conflict with or obstruct implementation of applicable air quality plans
- result in a cumulatively considerable net increase of any criteria pollutant for which the Project region is in nonattainment under an applicable federal or state ambient air quality standard
- expose sensitive receptors to substantial pollutant concentrations
- result in other emissions (such as those leading to odors) adversely affecting a substantial number of people

Specific Thresholds of Significance

This EIR applies the following air quality thresholds:

Air Quality Plan Consistency

<u>Construction and Operation</u>

The following qualitative threshold is used to evaluate the significance of air quality management plan consistency impacts resulting from implementation of the Project:

Construction and operation of buildings, appliances, equipment, and vehicles would not adhere to the measures and guidance included in BAAQMD 2017 Bay Area Clean Air Plan.

Criteria Air Pollutants

<u>Construction and Operation</u>

The BAAQMD 2022 *CEQA Air Quality Guidelines* are used in this analysis to evaluate air quality. **Table 3.3-3** shows the significance thresholds for Project criteria air pollutants and precursor emissions being used for the purposes of this analysis. These thresholds represent the levels at which a Project's individual emissions of criteria air pollutants or precursors would result in a cumulatively considerable contribution to the SFBAAB's existing air quality conditions. For the purposes of this analysis, the Project would result in a significant impact if Project emissions would exceed thresholds as shown in **Table 3.3-3**.

Table 3.3-3. BAAQMD Air Quality Significance Thresholds

	Construction Thresholds	Operational Thresholds	
Pollutant	**Average Daily Emissions (lbs/day)**	**Average Daily Emissions (lbs/day)**	**Maximum Annual Emissions (tons/year)**
ROG	54	54	10
NO_X	54	54	10
PM_{10}	82 (exhaust)	82	15
$PM_{2.5}$	54 (exhaust)	54	10

Source: BAAQMD 2023a ~~2022a~~

Key: ROG = reactive organic gases, NO_X = nitrogen oxides, PM_{10} = particulate matter 10 microns in diameter or less, $PM_{2.5}$ = particulate matter 2.5 microns or less in diameter; lbs/day = pounds per day

Toxic Air Containments

Construction and Operation

For health risks associated with TAC and $PM_{2.5}$ emissions, the BAAQMD 2022 *CEQA Guidelines* state a project would result in a significant impact if any of the following thresholds are exceeded during construction or operation:

- Noncompliance with Qualified Community Risk Reduction Plan
- Increased cancer risk of greater than 10 in a million
- Increased noncancer risk of greater than 1 HI (Chronic or Acute)
- Ambient $PM_{2.5}$ increase of greater than 0.3 µg/m^3 annual average

In addition, a project would have a cumulatively considerably impact associated with health risks from TAC and $PM_{2.5}$ emissions if the aggregate total emissions of all past, present, and foreseeable future sources within a 1,000-foot radius of the property line of the source plus the project's contribution exceed any of the following thresholds:

- Noncompliance with Qualified Community Risk Reduction Plan
- Increased cancer risk of greater than 100 in a million
- Increased noncancer risk of greater than 10 HI (Chronic or Acute)
- Ambient $PM_{2.5}$ increase of greater than 0.8 µg/m^3 annual average

Odor Sources

Construction and Operation

The BAAQMD provides minimum distances for siting of new odor sources as shown in **Table 3.3-4.** A significant impact would occur if the project would involve the operation of an odor source that would be located closer to sensitive receptors than the screen distances shown in **Table 3.3-4** or if five confirmed complaints per year averaged over 3 years have been received regarding odors associated with the project.

Table 3.3-4. BAAQMD Odor Source Thresholds

Odor Source	Minimum Distance for Less-than-Significant Odor Impacts (in miles)
Wastewater Treatment Plant	2
Wastewater Pumping Facilities	1
Sanitary Landfill	2
Transfer Station	1
Composting Facility	1
Petroleum Refinery	2
Asphalt Batch Plant	2
Chemical Manufacturing	2
Fiberglass Manufacturing	1
Painting/Coating Operations	1
Rendering Plant	2

BAAQMD 2022a, Table 5-4

3.3.4 Impact Analysis

Impact AQ-1: Conflict with or obstruct implementation of the applicable air quality plan **(Significant and Unavoidable)**

Construction

The most recently adopted air quality plan in the SFBAAB is the 2017 Clean Air Plan (BAAQMD 2017a ~~2017b~~). The 2017 Clean Air Plan is a roadmap showing how the San Francisco Bay Area will achieve compliance with the State one-hour ozone standard as expeditiously as practicable, and how the region will reduce transport of ozone and ozone precursors to neighboring air basins. The 2017 Clean Air Plan does not include control measures that apply directly to construction and operation of individual development projects. Instead, the control strategy includes stationary-source control measures to be implemented through the BAAQMD regulations; mobile-source control measures to be implemented through incentive programs and other activities; and transportation control measures to be implemented through transportation programs in cooperation with the Metropolitan Transportation Commission (MTC), local governments, transit agencies, and others. The 2017 Clean Air Plan focuses on two paramount goals, both consistent with the mission of BAAQMD:

- Protect air quality and health at the regional and local scale by attaining all national and state air quality standards and eliminating disparities among Bay Area communities in cancer health risk from TACs; and
- Protect the climate by reducing Bay Area GHG emissions to 40 percent below 1990 levels by 2030, and 80 percent below 1990 levels by 2050.

Under BAAQMD's methodology, a determination of consistency with the *CEQA Guidelines* thresholds should demonstrate that a project:

- Supports the primary goals of the 2017 Clean Air Plan;
- Includes applicable control measures from the 2017 Clean Air Plan; and
- Does not disrupt or hinder implementation of any 2017 Clean Air Plan control measures.

Seismic Retrofit Construction

On an individual project basis, consistency with BAAQMD quantitative thresholds is interpreted as demonstrating consistency with the 2017 Clean Air Plan's goals. As discussed under Impact AQ-2 below and summarized in **Table 3.3-5** and **Table 3.3-6**, Seismic Retrofit Construction would result in exceedances of BAAQMD thresholds for criteria air pollutants even with implementation of **Mitigation Measure AQ-1** and, thus, would conflict with the BAAQMD 2017 Clean Air Plan goal to attain established air quality standards. Therefore, Seismic Retrofit Construction would conflict with or obstruct the implementation of an applicable air quality plan, and impacts would be significant and unavoidable.

Conservation Measures Construction

<u>Ogier Ponds CM</u>

On an individual project basis, consistency with BAAQMD quantitative thresholds is interpreted as demonstrating consistency with the BAAQMD 2017 Clean Air Plan goals. As discussed under Impact AQ-2 below and summarized in **Table 3.3-7** and **Table 3.3-8**, Ogier Ponds CM construction would result in exceedances of BAAQMD thresholds for criteria air pollutants even with implementation of **Mitigation Measure AQ-1** and, thus, would conflict with the BAAQMD 2017 Clean Air Plan goal to attain established air quality standards. Therefore, Ogier Ponds CM construction would conflict with or obstruct the implementation of an applicable air quality plan, and impacts would be significant and unavoidable.

~~North Channel Extension~~

~~On an individual project basis, consistency with BAAQMD quantitative thresholds is interpreted as demonstrating consistency with the BAAQMD 2017 Clean Air Plan goals. As discussed under Impact AQ-2 below, North Channel Extension construction would not result in exceedances of BAAQMD thresholds for criteria air pollutants and, thus, would not conflict with the BAAQMD 2017 Clean Air Plan goal to attain established air quality standards. Therefore, North Channel Extension construction would not conflict with or obstruct the implementation of an applicable air quality plan, and impacts would be less than significant.~~

<u>Sediment Augmentation Program</u>

On an individual project basis, consistency with BAAQMD quantitative thresholds is interpreted as demonstrating consistency with the BAAQMD 2017 Clean Air Plan goals. As discussed under Impact AQ-2 below and summarized in **Table 3.3-9** and **Table 3.3-10**, Sediment Augmentation Program construction would <u>not</u> result in exceedances of BAAQMD thresholds for criteria air pollutants<u>,</u> ~~even with implementation of **Mitigation Measure AQ-1**~~ and, thus, would <u>not</u> conflict with the BAAQMD 2017 Clean Air Plan goal to attain established air quality standards. Therefore, Sediment Augmentation Program construction would <u>not</u> conflict with or obstruct the implementation of an applicable air quality plan, and impacts would be <u>less than</u> significant ~~and unavoidable~~.

Phase 2 Coyote Percolation Dam CM

On an individual project basis, consistency with BAAQMD quantitative thresholds is interpreted as demonstrating consistency with the BAAQMD 2017 Clean Air Plan goals. As discussed under Impact AQ-2 below and summarized in **Table 3.3-11** ~~and **Table 3.3-13**~~, Phase 2 Coyote Percolation Dam CM construction would not result in exceedances of BAAQMD thresholds for criteria air pollutants and, thus, would not conflict with the BAAQMD 2017 Clean Air Plan goal to attain established air quality standards. Therefore, Phase 2 Coyote Percolation Dam CM construction would not conflict with or obstruct the implementation of an applicable air quality plan, and impacts would be less than significant.

Operations and Maintenance

As discussed in Section 3.3.3, *Methodology and Approach to Impact Analysis*, post-construction operations and maintenance of the Anderson Dam Facilities and Conservation Measures, as well as FAHCE Adaptive Management, would result in negligible air pollutant emissions. Therefore, operational impacts with regard to consistency with an applicable air quality plan would be less than significant.

Significance Conclusion Summary

The criteria air pollutant emissions from construction of the Seismic Retrofit component and~~,~~ Ogier Ponds CM~~, and the Sediment Augmentation Program~~ would exceed BAAQMD thresholds. ~~As described under Impact AQ-2, implementation~~ Implementation of **Mitigation Measure AQ-1** would require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. However, even with implementation of **Mitigation Measure AQ-1**, construction of the Seismic Retrofit component~~, Ogier Ponds CM, and the Sediment Augmentation Program~~ would exceed BAAQMD thresholds for ROG and NOx, and construction of the Ogier Ponds CM would exceed the BAAQMD threshold for NO_X. As such, Project construction would conflict with the BAAQMD 2017 Clean Air Plan goal to attain established air quality standards, while Project operation would not exceed any BAAQMD thresholds for the various criteria air pollutants. Therefore, the Project overall would conflict with or obstruct the implementation of an applicable air quality plan, and impacts would be **significant and unavoidable**.

Mitigation Measures

Mitigation Measure AQ-1: Implement Construction Criteria Air Pollutants Reduction Measures

Prior to any ground disturbing and construction activities, Valley Water and/or its contractor will implement construction-related criteria pollutant emission reduction measures and include all such requirements in applicable bid documents, purchase orders, and contracts ~~constructs~~ with successful contractors demonstrating the ability to supply the compliant on-or off-road construction equipment for use. The reduction measures to implement and include on such documentation are as follows:

a. Ensure all off-road construction equipment with greater than 25 hp and operating for more than 20 hours total over the entire duration of construction activities have engines that meet or exceed either USEPA or CARB Tier 4 Final offroad emission standards. In the event that a Tier 4 final engine is not readily available for a specialized piece of equipment, the contractor must demonstrate its attempts to secure a Tier 4 engine, prior to the use of any such engine.

b. Ensure that all on-road trucks and boat engines used during construction are of model year 2010 or newer.

c. Minimize idling time either by shutting equipment off when not in use or reducing the time of idling to no more than 2 minutes. Provide clear signage that posts this requirement for workers at the entrances to the site and develop an enforceable mechanism to monitor idling time to ensure compliance with this measure.

d. Require that all construction equipment is maintained and properly tuned in accordance with manufacturer's specification. Equipment should be checked by a certified mechanic and determined to be running in proper condition prior to operation.

Impact AQ-2: A cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard (Significant and Unavoidable)

Construction

Seismic Retrofit Construction

The Seismic Retrofit component would generate criteria air pollutant and/or pre-cursors of criteria air pollutants emissions during the construction period compared to the existing baseline conditions at the time of the EIR preparation modified by the FOCP implementation. As described above, the criteria air pollutant emissions were estimated for off-road equipment, on-road vehicles, and in-water boats and barges expected to be used during the construction phases. In addition, criteria air pollutant emissions related to blasting were estimated.

Table 3.3-5 summarizes the estimated maximum daily average emissions of ROG, NO_X, PM_{10} exhaust, and $PM_{2.5}$ exhaust during construction of the Seismic Retrofit component**.** As shown in **Table 3.3-5**, Seismic Retrofit construction emissions would exceed the BAAQMD average daily thresholds for ROG in Year 1 through Year 6 and for NOx in Year 1 through Year 7. Therefore, criteria air pollutant emissions from construction of the Seismic Retrofit component would be significant.

However, implementation of **Mitigation Measure AQ-1**, described under Impact AQ-1 above, would require all construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. **Table 3.3-6** summarizes the estimated mitigated maximum daily average emissions of ROG, NO_X, PM_{10} exhaust, and $PM_{2.5}$ exhaust during construction of the Seismic Retrofit component**.** As shown in **Table 3.3-6,** mitigated Seismic Retrofit construction emissions would exceed the BAAQMD average daily thresholds for ROG in Year 1 and for NOx in Year 2 through Year 6. Therefore, Seismic Retrofit cumulative construction criteria pollutant impacts related to air pollutant emissions and consistency with associated air quality standards would be significant and unavoidable.

Table 3.3-5. Summary of Modeled Emissions of Criteria Air Pollutants by Year for Seismic Retrofit Construction

	ROG	NO_X	PM_{10} (exhaust)	$PM_{2.5}$ (exhaust)
Construction Year	**Average Daily Emissions (lbs/day)**			
Year 1	398	137 ~~138~~	41	32
Year 2	88	996	33	32
Year 3	82	93	32	30
Year 4	92	1,013 ~~1,015~~	34	32
Year 5	83	920 ~~922~~	30	29
Year 6	86	981 ~~983~~	30	29
Year 7	11	83 ~~84~~	2	2
Maximum Average Daily Emissions	**398**	**1,013** ~~**1,015**~~	**41**	**32**
BAAQMD Thresholds of Significance (average daily emissions)	54	54	82	54

Conservation Measures Construction

The emissions from the construction associated with the Conservation Measures components were analyzed using similar methodologies as the Seismic Retrofit component construction.

Ogier Ponds CM

Table 3.3-7 summarizes the estimated maximum daily average emissions of ROG, NO_X, PM_{10} exhaust, and $PM_{2.5}$ exhaust during construction of the Ogier Ponds CM**.** As shown in **Table 3.3-7**, Ogier Ponds CM construction emissions would exceed the BAAQMD average daily threshold for NOx in Years 6 through Year 8. Therefore, criteria air pollutant emissions from construction of the Ogier Ponds CM would be significant.

However, implementation of **Mitigation Measure AQ-1**, described under Impact AQ-1 above, would require all construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. **Table 3.3-8** summarizes the estimated mitigated maximum daily average emissions of ROG, NO_X, PM_{10} exhaust, and $PM_{2.5}$ exhaust during construction of the Ogier Ponds CM**.** As shown in **Table 3.3-8,** mitigated Ogier Ponds CM construction emissions would exceed the BAAQMD average daily thresholds for NO_X in Year 6 and Year 7. Therefore, Ogier Ponds CM cumulative construction criteria pollutant impacts related to air pollutant emissions and consistency with associated air quality standards would be significant and unavoidable.

~~North Channel Extension~~

~~North Channel Extension was not analyzed for criteria air pollutant emissions given the short duration, small number of equipment and workers required, and lack of high-emissions activities. The North Channel Extension would consist of grading over one dry season and construction work over 2 months in Year 1, and planting of native vegetation over 2 months in Year 7. Work would require a maximum of 20 onsite workers at any one time and an average of 10 onsite workers for the duration of construction. Construction would require a bulldozer, motor grader, excavator, loader, dump, light trucks, and a water truck. Only minor material movement is expected to occur as part of grading for the channel extension and no other high-emissions activities would occur. The minimal amount of construction activity required for the North Channel Extension is unlikely to exceed BAAQMD's thresholds of significance on its own and would be less than significant.~~

Sediment Augmentation Program

Table 3.3-9 summarizes the estimated maximum daily average emissions of ROG, NO_X, PM_{10} exhaust, and $PM_{2.5}$ exhaust during construction of the Sediment Augmentation Program**.** As shown in **Table 3.3-9**, Sediment Augmentation Program construction emissions would not exceed the BAAQMD average daily threshold for any criteria air pollutant ~~NO_X during every year of construction from Year 2 through Year 15~~. Therefore, criteria air pollutant emissions from construction of the Sediment Augmentation Program would be less than significant.

Additionally ~~However~~, implementation of **Mitigation Measure AQ-1**, described under Impact AQ-1 above, would require all construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. **Table 3.3-10** summarizes the estimated mitigated maximum daily average emissions of ROG, NO_X, PM_{10} exhaust, and $PM_{2.5}$ exhaust during construction of the Sediment Augmentation Program**.** As shown in **Table 3.3-10,** mitigated Sediment Augmentation Program construction emissions would not exceed the BAAQMD average daily thresholds any criteria air pollutant ~~for NOx during every year of construction from~~

~~Year 2 through Year 15~~. Therefore, Sediment Augmentation Program cumulative construction criteria pollutant impacts related to air pollutant emissions and consistency with associated air quality standards would be less than significant ~~and unavoidable~~.

Fugitive Dust Emissions

Due to the size and length of Project construction and its proximity to sensitive receptors, fugitive dust emission other than from blasting would be significant even with BMP AQ-1. Implementation of **Mitigation Measure AQ-3** described below, would be required. **Mitigation Measure AQ-3** would implement BAAQMD's Enhanced Construction BMPs, which includes planting vegetative ground cover or using a soil stabilizer, applying gravel to unpaved roads, and minimizing the simultaneous occurrence of excavation, grading, and ground-disturbing construction activities on the same area at any one time. Implementation of **Mitigation Measure AQ-3**, in addition to BMP AQ-1, would reduce fugitive dust emissions by implementing all feasible fugitive dust control measures recommended by BAAQMD and additional measures to control fugitive dust from blasting. Nevertheless, fugitive dust emissions from Seismic Retrofit and Conservation Measure construction are likely to remain high near sensitive receptors, and this impact would be significant and unavoidable.

Unmitigated blasting emissions and mitigated blasting emissions are shown in **Table 3.3-12**. Mitigated blasting emissions account for implementation of **Mitigation Measure AQ-2** which would require the use of wind screens during blasting to reduce the PM emissions associated with blasting. The blasting fugitive PM emissions would be significant without mitigation; however, implementation of **Mitigation Measure AQ-2**, described below, would be required. **Mitigation Measure AQ-2** would require the installation of wind screens during blasting activities to reduce fugitive dust emissions. Implementation of **Mitigation Measure AQ-2** would reduce blasting emissions to less than significant levels with mitigation incorporated.

Table 3.3-12. Blasting Fugitive Dust Emissions

Operations and Maintenance

As discussed in Section 3.3.3, *Methodology and Approach to Impact Analysis*, above, post-construction operations and maintenance of the Anderson Dam Facilities and Conservation Measures, as well as FAHCE Adaptive Management, would result in negligible criteria air pollutant emissions. Therefore, regional air quality standards attainment impacts would be less than significant, and no mitigation is required.

Significance Conclusion Summary

Construction of the Seismic Retrofit components and~~,~~ Ogier Ponds CM~~, and the Sediment Augmentation Program,~~ would exceed the BAAQMD average daily thresholds for criteria air pollutants, while construction of the Sediment Augmentation Program and Phase 2 Coyote Percolation Dam CM and Project operational impacts related to criteria air pollutants would be less than significant. Specifically, Seismic Retrofit construction emissions would exceed the BAAQMD average daily thresholds for ROG in Year 1 through Year 6 and for NOx in Year 1 through Year 7. Ogier Ponds CM construction emissions would exceed the BAAQMD average daily threshold for NO_X in Year 6 and Year 7. ~~Sediment Augmentation Program construction emissions would exceed the BAAQMD average daily threshold for NO_X during every year of construction from Year 2 through Year 15.~~ Construction of the ~~North Channel Extension and~~ Phase 2 Coyote Percolation Dam CM and Sediment Augmentation Program would not exceed the BAAQMD average daily thresholds for criteria air pollutants. **Table 3.3-13** summarizes the overall Project construction emissions. As shown in **Table 3.3-13**, overall Project construction emissions would exceed the BAAQMD average daily threshold for ROG during Year 1 through Year 6 and for NO_X during Year 1 through Year 8 ~~15~~.

Source: Appendix E: Table 50

Key: ROG = reactive organic gases, NO_X = nitrogen oxides, PM_{10} = particulate matter 10 microns in diameter or less, $PM_{2.5}$ = particulate matter 2.5 microns or less in diameter; lbs/day = pounds per day

In addition, construction-related fugitive dust impacts other than from blasting would remain significant even with implementation of BAAQMD basic BMPs (BMP AQ-1) and **Mitigation Measure AQ-3**, because emissions would remain high near sensitive receptors for a relatively long duration. Fugitive dust impacts from blasting emissions would be less than significant with implementation of **Mitigation Measure AQ-2**. **Mitigation Measure AQ-2**, described below, would require the installation of wind screens during blasting activities to reduce fugitive dust emissions. **Mitigation Measure AQ-3**, described below, would implement BAAQMD's Enhanced Construction BMPs, which includes planting vegetative ground cover or using a soil stabilizer, applying gravel to unpaved roads, and minimizing the simultaneous occurrence of excavation, grading, and ground-disturbing construction activities on the same area at any one time.

Implementation of **Mitigation Measure AQ-1**, described under Impact AQ-1 above, would require all construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. Mitigated Seismic Retrofit construction emissions would exceed the BAAQMD average daily thresholds for ROG in Year 1 and for NOx in Year 2 through Year 6. Mitigated Ogier Ponds CM construction emissions would exceed the BAAQMD average daily thresholds for NO_X in Year 6 and Year 7. ~~Mitigated Sediment Augmentation Program construction emissions would exceed the BAAQMD average daily thresholds for NO_X during every year of construction from Year 2 through Year 15.~~ **Table 3.3-14** summarizes the mitigated overall Project construction emissions. As shown in **Table 3.3-14**, mitigated overall Project construction emissions would exceed the BAAQMD average daily threshold for ROG during Year 1 ~~6~~ and for NO_X during Year 2 through Year 7 ~~15~~. Since criteria air pollutant exhaust emissions would remain above the BAAQMD significance threshold even with implementation of **Mitigation Measures AQ-1, AQ-2, and AQ-3**, the overall Project impact related to regional air quality, as well as fugitive dust emissions, would be **significant and unavoidable**.

These significant criteria air pollutant emissions could lead to increased concentrations of pollutants in the atmosphere and could result in health effects due to the increased emissions. TAC emissions are evaluated further in the HRA, and evaluated under Impact AQ-3 along with the primary $PM_{2.5}$ concentration. The ambient concentration of criteria pollutants is a result of complex atmospheric chemistry. Photochemical grid-based models simulate the chemical interactions and three-dimensional dispersion patterns on a regional, statewide, and national scale. These models are complex and require significant expertise, knowledge, and resources as they build on other third-party models and processing tools that characterize meteorology, emissions, and other environmental conditions, such as land cover, radiative properties, and boundary conditions. Use of these models is typically beyond the resources available for air quality analysis prepared pursuant to CEQA, and even if such an analysis was to be completed consideration would need be given to ensure the results would be meaningful based on modeling and data limitations. This information is not widely available and, where it is available, its use would be speculative.

$NO_{\cancel{o}x}$ and ROG are precursors to ozone, and NO_x, ROG, and sulfur oxides (SO_x) are precursors to secondarily formed $PM_{2.5}$. Chemical and physical processes transform some of these precursors to the criteria pollutant concentrations in the atmosphere. Multiple variables determine whether emissions of air pollutants from the project move and disperse in the atmosphere in a manner in which concentrations of criteria pollutants would become elevated and result in health impacts. A specific mass of precursor emissions does not equate to an equivalent concentration of the resultant ozone or secondary particulate matter in that area. The resulting health effects of ambient air concentrations are further based on a complex relationship of multiple variables and factors. The calculated health effects are dependent upon the concentrations of pollutants to which the receptors are exposed the number and type of exposure pathways for a receptor, and the intake parameters from a receptor, which vary based upon age and sensitivity (e.g., presence of pre-existing conditions). Health effects would be more likely for individuals with greater susceptibility to exposure, and the location of receptors relative to the project impacts would affect where the receptors are exposed to project-related pollutants.

The following is a summary of the health effects from ozone, $PM_{2.5}$ and PM_{10}. Meteorology and terrain play major roles in ozone formation, and conditions for maximum ozone generation occur on days with low wind speeds or stagnant air, warm temperature, and cloudless skies. Short-term exposure (lasting a few hours) to ozone at levels typically observed in the SFBAAB can result in health effects. When inhaled, $PM_{2.5}$ and PM_{10} can penetrate the human respiratory system's natural defenses and damage the respiratory tract. $PM_{2.5}$ and PM_{10} can increase the number and severity of asthma attacks and cause or aggravate bronchitis and other lung diseases. Whereas PM_{10} tends to collect in the upper portion of the respiratory system, $PM_{2.5}$ is so tiny that it can penetrate deeper in the lungs and damage lung tissues. Health effects of $PM_{2.5}$ include mortality (all causes), hospital admissions (respiratory, asthma, cardiovascular), emergency room visits (asthma), and acute myocardial infraction (non-fatal). For ozone, the endpoints are mortality, emergency room visits (respiratory), and hospital admissions (respiratory).

Since ROG and NO_x emissions will remain above the significance threshold, these emissions would be considered **significant and unavoidable**.

Mitigation Measures

AQ-1 Implement Construction Criteria Air Pollutants Reduction Measures

AQ-2 Implement Construction Blasting Fugitive Dust Emissions Reduction

Valley Water and/or its contractor will implement construction-related fugitive dust emission reduction measures and include all requirements in applicable bid documents, purchase orders, and contracts ~~constructs~~ with successful contractors demonstrating the ability to supply the blasting screens for use prior to any ground disturbing and construction activities. The Contractor will install three-sided wind screens during blasting activities. Wind screens should be made of a solid fabric or other material capable of catching at least 75 percent of particulate matter greater than 2.5 micrometers in diameter. Screens should be used in combination with watering of the blasting area.

AQ-3 Implement BAAQMD Enhanced Construction BMPs

To further reduce construction-related emissions that exceed the BAAQMD's thresholds of significance, Valley Water will require its construction contractors to comply with the following enhanced BMPs during construction:

- Vegetative ground cover (e.g., fast-germinating native grass seed) will be planted in disturbed areas as soon as possible in light of construction phasing and scheduling by Valley Water and watered appropriately until vegetation is established. Where vegetative ground cover is not feasible, soil stabilizer will be used.
- The simultaneous occurrence of excavation, grading, and ground-disturbing construction activities on the same area at any one time will be limited whenever feasible. Activities will be phased to reduce the amount of disturbed surfaces at any one time as permitted by construction phasing and scheduling.

Impact AQ-3: Expose sensitive receptors to substantial pollutant concentrations (Significant and Unavoidable)

Construction

Construction of the Seismic Retrofit component and Conservation Measures would generate TAC emissions and release $PM_{2.5}$ in proximity to nearby sensitive receptors. In order to determine the impacts of these TAC and $PM_{2.5}$ emissions exposure to sensitive receptors, an HRA was conducted following OEHHA and BAAQMD guidelines for comparison to BAAQMD's risk thresholds for projects (Appendix E). The analysis discusses risk with respect to receptors within 1,000 feet of each specific construction phase, as well as the total risk to receptors from construction of the Seismic Retrofit component and the Conservation Measures components regardless of distance between the activity and the receptor. Air pollution sensitive receptors in proximity to the Project area are discussed in Section 3.3.1.3, *Valley Water and Anderson Dam.* This evaluation does not include NOA. Refer to Section 3.10, *Hazards and Hazardous Materials*, for an evaluation of NOA.

Seismic Retrofit Construction

The results of the HRA for Seismic Retrofit construction are shown in **Table 3.3-15**. As shown in **Table 3.3-15**, emissions from Seismic Retrofit construction would exceed the BAAQMD thresholds for excess lifetime cancer risk, acute HI, and $PM_{2.5}$ concentrations. Therefore, Seismic Retrofit construction would expose receptors to substantial pollutant concentrations and impacts would be significant.

Implementation of **Mitigation Measures AQ-1 and AQ-2**, described under Impacts AQ-1 and AQ-2 above, would be required. **Mitigation Measure AQ-1** would require all diesel construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. **Mitigation Measure AQ-2** would require the installation of three-sided wind screens during blasting activities. **Table 3.3-16** summarizes the mitigated Seismic Retrofit construction HRA results. As shown in **Table 3.3-16**, mitigated Seismic Retrofit construction risks would still exceed the BAAQMD thresholds for excess lifetime cancer risk, acute HI, and $PM_{2.5}$ concentrations. Therefore, Seismic Retrofit construction would expose receptors to substantial pollutant concentrations and impacts would be significant and unavoidable.

Table 3.3-15. Summary of Seismic Retrofit Construction Health Risk Assessment Results

	Excess Lifetime Cancer Risk	Chronic HI	Acute HI	$PM_{2.5}$ Concentration

Conservation Measures Construction

Ogier Ponds CM

The results of the HRA for Ogier Ponds CM construction are shown in **Table 3.3-17**. As shown in **Table 3.3-17**, emissions from Ogier Ponds CM construction would not exceed the BAAQMD thresholds. Therefore, Ogier Ponds CM construction would not expose receptors to substantial pollutant concentrations and impacts would be less than significant.

Implementation of **Mitigation Measure AQ-1**, described under Impact AQ-1 above, would require all diesel construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. **Table 3.3-18** summarizes the mitigated Ogier Ponds CM construction HRA results. As shown in **Table 3.3-18**, mitigated Ogier Ponds CM construction risks would further reduce risk and would not exceed the BAAQMD thresholds. Therefore, Ogier Ponds CM construction would not expose receptors to substantial pollutant concentrations and impacts would remain less than significant.

~~North Channel Extension~~

~~North Channel Extension was not analyzed in the HRA. The North Channel Extension would consist of grading over one dry season and construction work over 2 months in Year 1, and planting of native vegetation over 2 months in Year 7. Work would require a maximum of 20 onsite workers at any one time and an average of 10 onsite workers for the duration of construction. Construction would require a bulldozer, motor grader, excavator, loader, dump, light trucks, and a water truck. Only minor material movement is expected to occur as part of grading for the channel extension and no other high-emissions activities would occur. This amount of construction activity is unlikely to exceed BAAQMD's significance thresholds for risk and hazards, and on its own would be less than significant.~~

Sediment Augmentation Program

The results of the HRA for Sediment Augmentation Program construction are shown in **Table 3.3-19**. As shown in **Table 3.3-19**, emissions from Sediment Augmentation Program construction would not exceed the BAAQMD thresholds for excess lifetime cancer risk and $PM_{2.5}$ concentrations. Therefore, Sediment Augmentation Program construction would not expose receptors to substantial pollutant concentrations and impacts would be less than significant.

Implementation of **Mitigation Measure AQ-1**, described under Impact AQ-1 above, would require all diesel construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. **Table 3.3-16** summarizes the mitigated Sediment Augmentation Program construction HRA results. As shown in **Table 3.3-16**, mitigated Sediment Augmentation Program construction risks would not exceed the BAAQMD thresholds for excess lifetime cancer risk ~~even~~ with mitigation. Therefore, Sediment Augmentation Program construction would not expose receptors to substantial pollutant concentrations and impacts would ~~be~~ remain less than significant ~~and unavoidable~~.

Phase 2 Coyote Percolation Dam CM

The results of the HRA for Phase 2 Coyote Percolation Dam CM construction are shown in **Table 3.3-21.** As shown in **Table 3.3-21**, emissions from Phase 2 Coyote Percolation Dam CM construction would not exceed the BAAQMD thresholds. Therefore, Phase 2 Coyote Percolation Dam CM construction would not expose receptors to substantial pollutant concentrations and impacts would be less than significant.

Implementation of **Mitigation Measure AQ-1**, described under Impact AQ-1 above, would require all diesel construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. **Table 3.3-22** summarizes the mitigated Phase 2 Coyote Percolation Dam CM HRA results. As shown in **Table 3.3-22**, mitigated Phase 2 Coyote Percolation Dam CM construction risks would further reduce risk and would not exceed the BAAQMD thresholds. Therefore, Phase 2 Coyote Percolation Dam CM construction would not expose receptors to substantial pollutant concentrations and impacts would remain less than significant.

Operations and Maintenance

As discussed in Section 3.3.3, *Methodology and Approach to Impact Analysis*, above, post-construction operations and maintenance of the Anderson Dam Facilities and Conservation Measures, as well as FAHCE Adaptive Management, would result in negligible TAC emissions. Therefore, operational impacts related to potential exposure to TACs would be less than significant, and no mitigation is required.

Significance Conclusion Summary

The results of the HRA for all Project construction activities, including the Seismic Retrofit components and Conservation Measures components, are shown in **Table 3.3-23**. Project operational impacts related to TAC emissions would be **less than significant.** Specifically, as shown in **Table 3.3-23**, Project construction activities related to these components would exceed BAAQMD's significance thresholds for excess lifetime cancer risk, acute HI, and $PM_{2.5}$ concentration.

Implementation of **Mitigation Measure AQ-1** and **Mitigation Measure AQ-2**, described under Impacts AQ-1 and AQ-2 above, would be required. **Mitigation Measure AQ-1** would require all diesel construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. **Mitigation Measure AQ-2** would require the installation of three-sided wind screens during blasting activities. **Table 3.3-24** summarizes the mitigated overall Project construction HRA results. As shown in **Table 3.3-24**, mitigated overall Project construction risks would exceed the BAAQMD thresholds for excess lifetime cancer risk, acute HI, and $PM_{2.5}$ concentration even with mitigation. Therefore, the Project overall would expose receptors to substantial pollutant concentrations, and impacts would be **significant and unavoidable**.

BAAQMD *CEQA Guidelines* establish an incremental $PM_{2.5}$ concentration CEQA significance level of 0.3 µg/m³, based on an annual average. There are also NAAQS and CAAQS s for $PM_{2.5}$. The $PM_{2.5}$ NAAQS include an annual average concentration of 12 µg/m³ and a 24-hour average concentration of 35 µg/m³ and are both based on the 8th highest concentration for that averaging time. The $PM_{2.5}$ CAAQS include an annual average concentration of 12 µg/m³, but the State has not established a 24-hour average $PM_{2.5}$ CAAQS. $PM_{2.5}$ concentrations due to construction activities at the MEI are shown in **Table 3.3-25**. The $PM_{2.5}$ concentrations associated with mitigated emissions from construction of the Project represent a small fraction of background and a small fraction of the NAAQS and CAAQS, which provides additional context of the fine particulate matter impacts. While incremental $PM_{2.5}$ concentrations exceed the CEQA significance level of 0.3 µg/m³ when the 8th highest concentrations at the MEI are added to the background concentrations, as shown in **Table 3.3-25**, the concentrations for the mitigated scenario would not exceed the NAAQS or CAAQS. Nevertheless, since Project $PM_{2.5}$ concentration would exceed the BAAQMD threshold of 0.3 µg/m³ with mitigation, this impact would be **significant and unavoidable.**

Table 3.3-25. Background Fine Particulate Matter Concentrations in the Project Area

Pollutant	Averaging Period	AAQS ($\mu g/m^3$)	Form of Standard	Background Concentration [1] ($\mu g/m^3$)	Unmitigated Project Contribution at $PM_{2.5}$ MEI[2] ($\mu g/m^3$)	Mitigated Project Contribution at $PM_{2.5}$ MEI[2] ($\mu g/m^3$)
PM2.5	24-Hour	35 (NAAQS)	8th Highest Maximum Concentration	25 32	1.6 10.3[4]	0.84 ~~1.32~~
PM2.5	Annual	12.0 (NAAQS[3] & CAAQS)	Annual Mean	8.9 10.3	0.67 1.0	0.35 ~~0.48~~

Source: Appendix E: Summary Table P ~~K~~.

Notes:

[1] Background concentrations are USEPA design values from ~~2019-~~2021-2023 for the monitor located at San José – Knox Avenue, the closest $PM_{2.5}$ monitor to the Project area.

[2] Emission rates modeled as emissions in lb/year converted to g/s for 365 days (for comparison to the annual NAAQS) and for a typical day in Year 4 (the Seismic Retrofit construction year of maximum unmitigated and mitigated $PM_{2.5}$ emissions). Emission rates conservatively include fugitive $PM_{2.5}$. The Seismic Retrofit construction contribution was evaluated at the Project $PM_{2.5}$ MEI.

[3] On February 7, 2024, the U.S. Environmental Protection Agency (EPA) strengthened the NAAQS for fine particle pollution ($PM_{2.5}$) by revising the level of the primary (health-based) annual $PM_{2.5}$ standard to 9.0 $\mu g/m^3$. The effective date of the new standard was May 6, 2024. However, the 12.0 $\mu g/m^3$ standard was the standard at the time of Draft EIR preparation, and the Project's unmitigated and mitigated contribution remains well below both the former and new NAAQS standard.

[4] The original value of 10.3 $\mu g/m^3$ was an error due to an erroneously high number of construction hours for fugitive dust emissions, which was corrected during remodeling based on Project revisions. This error was only specific to the Seismic Retrofit.

Key: AAQS = Ambient Air Quality Standards; CAAQS = California Ambient Air Quality Standards; MEI = maximum exposed individual; NAAQS = National Ambient Air Quality Standards; $PM_{2.5}$ = particulate matter 2.5 microns or less in diameter; $\mu g/m^3$ = micrograms per cubic meter

Mitigation Measures

AQ-1 Implement Construction Criteria Air Pollutants Reduction Measures

AQ-2 Implement Construction Blasting Fugitive Dust Emissions Reduction

Impact AQ-4: Other emissions adversely affecting a substantial number of people **(Less than Significant)**

Construction

Seismic Retrofit Construction

During Seismic Retrofit construction, odors would be emitted from diesel exhaust generated by construction equipment and haul trucks. Construction and hauling activities near existing receptors would be temporary, intermittent, and only during construction hours. Additionally, the diesel exhaust emissions and the associated odors would be diffusive in nature (i.e., spread out over several large work areas) and would not persist upon completion of construction.

When the reservoir and channels are fully dewatered during construction, odors could be emitted from exposed organic matter. However, the exposed organic matter is not anticipated to be a permanent odor source because the sediment would dry out or be removed during clearing and grubbing to allow for a clear construction site. Odors could be emitted from the short-term stockpiling of sediment materials. However, through the implementation of BMP AQ-2, Seismic Retrofit construction activities would avoid stockpiling odorous material near sensitive receptors.

BAAQMD has not developed an odor screening distance for this Project land use type, which suggests that construction and operation of reservoirs/waterbodies are not common sources of odor. In addition, in comparison to the odor screening distances, the predominant winds are from the north-northwest. While there are nearby residences to the south and southeast of the Project area (i.e., less than 1 mile), those locations would be potentially downwind of active construction work areas on a temporary basis and are unlikely to experience substantial or long-term odors from the Project.

Based on data provided by BAAQMD through a public records request in which Ramboll requested all publicly available odor complaints in Morgan Hill, California, for the most recent and available three-year period (i.e., February 2020 through February 2023), BAAQMD has received zero confirmed odor complaints regarding odor associated with Anderson Dam (including Anderson Lake and associated recreational activities) (BAAQMD 2023b ~~2023a~~). Thus, based on the odor complaint history and the temporary nature of construction activities, Seismic Retrofit construction would not generate objectionable odors affecting a substantial number of people, and impacts would be less than significant.

Conservation Measures Construction

During Conservation Measure construction, odors would be emitted from diesel exhaust generated by construction equipment and haul trucks. Construction and hauling activities near existing receptors would be temporary, intermittent, and only during construction hours. Additionally, the diesel exhaust emissions and associated odors would be diffusive in nature (i.e., spread out over several large work areas) and would not persist upon completion of construction.

When the reservoir and channels are fully dewatered during construction, odors could be emitted from exposed organic matter. However, the exposed organic matter is not anticipated to be a permanent odor source, because the sediment would dry out or be removed during clearing and grubbing to allow for a clear construction site. Odors could be emitted from the short-term stockpiling of the sediment materials. However, through the implementation of BMP AQ-2, Conservation Measure construction activities would avoid stockpiling odorous material nearby sensitive receptors. Additionally, since the Conservation Measures Project areas are smaller in size and scale than the Seismic Retrofit Project area, the number of odor complaints received for Anderson Dam is expected to be representative for the Conservation Measures. Thus, based on the odor complaint history and the temporary nature of construction activities, Conservation Measures construction would not generate objectionable odors affecting a substantial number of people, and impacts would be less than significant.

Operations and Maintenance

As discussed in Section 3.3.3, *Methodology and Approach to Impact Analysis*, above, post-construction operations and maintenance of the Anderson Dam Facilities and Conservation Measures, as well as FAHCE Adaptive Management, would not result in emissions of odor. Therefore, there would be no operational impact related to exposure to odors.

Significance Conclusion Summary

As described above, construction equipment would emit diesel exhaust odors, and the disturbance of soils and dewatered channels and reservoirs could emit organic matter odors. These odors would be temporary and intermittent. Implementation of BMP AQ-2 would require construction avoid stockpiling of odorous material near sensitive receptors. Currently, there have been no reported odor complaints to BAAQMD. Construction odors are not anticipated to be notably different for the Project compared to the existing baseline conditions at the time of the EIR preparation modified by the FOCP implementation. Odors associated with operations and maintenance are not expected. Thus, based on the odor complaint history, implementation of BMP AQ-2, and the temporary nature of construction activities, the overall Project impact related to exposure to odors would be **less than significant**.

Mitigation Measures

No mitigation is required.

3.3.5 Cumulative Impacts

The cumulative impact geographic study area for air quality is the Santa Clara Valley Subregion of the SFBAAB. The Santa Clara Valley Subregion is bounded by the San Francisco Bay to the north and by mountains to the east, south, and west. The Santa Clara Valley has a high concentration of industrial activity at its northern end in Silicon Valley. In addition, the Santa Clara Valley's large population and many work-site destinations generate the highest levels of mobile-sourced emissions of any subregion in the SFBAAB (BAAQMD 2017a ~~2017c~~).

The approach to the cumulative impacts analysis and list of foreseeable future projects, programs, and plans considered in the cumulative impact analysis is included in Section 3.0.5, *Approach to Cumulative Impacts*.

This section describes the Project's contribution to cumulative air quality impacts, as summarized in **Table 3.3-26**. Cumulative impact thresholds for air quality are the same as the impact thresholds presented in Section 3.3.3.8, *Thresholds of Significance*.

Table 3.3-26. Summary of Project Impact Contribution to Cumulative Air Quality Impacts

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact AQ-1: Conflict with or obstruct implementation of the applicable air quality plan	No ~~Yes~~	Y~~es~~	C~~C~~	MM AQ-1	Y~~es~~
Cumulative Impact AQ-2: Cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard	No ~~Yes~~	Y~~es~~	C~~C~~	MM AQ-1 MM AQ-2 MM AQ-3	Y~~es~~
Cumulative Impact AQ-3: Expose sensitive receptors to substantial pollutant concentrations	No	No	NCC	MM AQ-1 MM AQ-2	No
Cumulative Impact AQ-4: Other emissions adversely affecting a substantial number of people	N~~o~~	N~~o~~	NC~~C~~	N/A	N~~o~~

Key: CC = cumulatively considerable; MM = Mitigation Measure; N/A = not applicable; NCC = not cumulatively considerable

Cumulative Impact AQ-1: Conflict with or obstruct implementation of the applicable air quality plan **(Cumulatively Considerable)**

The SFBAAB is in non-attainment for federal standards of ozone and $PM_{2.5}$ and in non-attainment for the State standard for ozone, $PM_{2.5}$, and PM_{10}. The SFBAAB is in attainment of all other federal and State standards. Construction of the Seismic Retrofit components and Conservation Measures of the Project would exceed the BAAQMD average daily thresholds for criteria air pollutants, which would conflict with or obstruct implementation of the applicable air quality plan.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction or operation activities overlap within the same timeframe as the construction activities for the Project.

Cumulative Effects of Project with the FOCP

The FOCP would be completed before construction activities for the Project begin; therefore, these two projects would not result in cumulative impacts related to criteria air pollutants. There would be no cumulatively significant effect.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most of the other reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, would occur within the SFBAAB. Construction or operation of future projects, programs, and plans could overlap with the <u>8</u> ~~15~~-year construction schedule that Seismic Retrofit components and Conservation Measures construction would occur. Construction of the Project would exceed the BAAQMD average daily thresholds for criteria air pollutants, which would conflict with or obstruct implementation of the applicable air quality plan. In combination with construction or operation occurring at the same time from <u>probable</u> ~~probably~~ future projects, plans, and programs, Project construction could create localized areas of unhealthy air pollution levels or air quality nuisances, which would further conflict with or obstruct implementation of the applicable air quality plan. Therefore, the cumulative impact resulting from the Project in combination with other probable future projects would be cumulatively significant, and the Project's contribution would be cumulatively considerable.

Significance Conclusion Summary

Valley Water would reduce the Project's incremental contribution to cumulative impacts on criteria air pollutants through implementation of **Mitigation Measure AQ-1**, which would require all construction equipment to be equipped with Tier 4 engines and would require all on-road <u>truck</u> engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. Construction of the Seismic Retrofit components and Conservation Measures would exceed the BAAQMD average daily thresholds for criteria air pollutants without mitigation and this impact would be significant and cumulatively considerable impact before mitigation. With implementation of **Mitigation Measure AQ-1**, construction of the Seismic Retrofit components and Conservation Measures would exceed the BAAQMD average daily thresholds for criteria air pollutants with mitigation. The Project's contribution to cumulative impacts on criteria air pollutants remains **cumulatively considerable**.

Mitigation Measures

AQ-1 Construction Air Quality Criteria Air Pollutant Mitigation Measure

***Cumulative Impact AQ-2: Cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard* (Cumulatively Considerable)**

The SFBAAB is in non-attainment for federal standards of ozone and $PM_{2.5}$ and in non-attainment for the State standard for ozone, $PM_{2.5}$, and PM_{10}. The SFBAAB is in attainment of all other federal and State standards. Construction of the Seismic Retrofit components and Conservation Measures of the Project would exceed the BAAQMD average daily thresholds for criteria air pollutants, which could result in the net increase of criteria air pollutants.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction or operation activities overlap within the same timeframe as the construction activities for the Project.

Cumulative Effects of Project with the FOCP

The FOCP would be completed before construction activities for the Project begin. Together, these two projects would not result in cumulative impacts related to criteria air pollutants. There would be no cumulative effect.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most of the other reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, would occur within the SFBAAB. Construction or operation of future projects, programs, and plans could overlap with the 8 ~~15~~-year construction schedule that Seismic Retrofit components and Conservation Measures construction would occur. Construction of the Project would exceed the BAAQMD average daily thresholds for criteria air pollutants. In combination with construction or operation occurring at the same time from probable future projects, plans, and programs, the cumulative impact would be significant. The construction of other projects could generate fugitive dust in addition to fugitive dust from the Project and the cumulative impact of fugitive dust would be significant Therefore, the cumulative impact on the net increase of any criteria air pollutants resulting from the Project in combination with other probable future projects is cumulatively significant, and the Project's contribution would be cumulatively considerable.

Significance Conclusion Summary

Valley Water would reduce the Project's incremental contribution to cumulative impacts on criteria air pollutants through implementation of **Mitigation Measure AQ-1**, which would require all construction equipment to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** would also minimize construction equipment idling time and require regular maintenance for all equipment. Construction of the Seismic Retrofit components and Conservation Measures would exceed the BAAQMD average daily thresholds for criteria air pollutants without mitigation and this impact would be a significant and cumulatively considerable impact before mitigation. With implementation of **Mitigation Measure AQ-1**, construction of the Seismic Retrofit components and Conservation Measures would exceed the BAAQMD average daily thresholds for criteria air pollutants with mitigation. Fugitive dust impacts from blasting emissions would be less than significant with implementation of **Mitigation Measure AQ-2**, which would require the installation of wind screens during blasting activities to reduce fugitive dust emissions. **Mitigation Measure AQ-3** would implement BAAQMD's Enhanced Construction BMPs, which includes planting vegetative ground cover or using a soil stabilizer, and minimizing the simultaneous occurrence of excavation, grading, and ground-disturbing construction activities on the same area at any one time. Nevertheless, even with mitigation, construction-related fugitive dust impacts would be cumulatively considerable**.** The Project's contribution to cumulative impacts on criteria air pollutants remains **cumulatively considerable.**

Mitigation Measures

AQ-1 Implement Construction Criteria Air Pollutants Reduction Measures

AQ-2 Implement Construction Blasting Fugitive Dust Emissions Reduction

AQ-3 Implement BAAQMD Enhanced Construction BMPs

Cumulative Impact AQ-3: Expose sensitive receptors to substantial pollutant concentrations (Not Cumulatively Considerable)

Construction of the Seismic Retrofit components and Conservation Measures of the Project would exceed the BAAQMD thresholds for risks and hazards, which would expose sensitive receptors to substantial pollutant concentrations. Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction or operation activities overlap within the same timeframe as the construction activities for the Project.

Cumulative Effects of Project with the FOCP

The FOCP would be completed before construction activities for the Project begin; therefore, these two projects would not result in cumulative impacts related to criteria air pollutants. There would be no cumulative effect.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

As discussed under Section 3.3.3.8, *Thresholds of Significance*, a project would have a cumulatively considerably impact associated with health risks from TAC and $PM_{2.5}$ emissions if the aggregate total emissions of all past, present, and foreseeable future sources within a 1,000-foot radius of the property line of the source plus the project's contribution exceed the lifetime cancer risk of more than 100 in a million, chronic non-cancer HI greater than 10.0, and an incremental increase in the annual average $PM_{2.5}$ concentration of greater than 0.8 $\mu g/m^3$. The cumulative impact for the HRA was evaluated at the MEI for Project construction combined with the health risk from stationary and roadway sources within 1,000 feet based on health risk data provided by the BAAQMD. The MEI is the receptor with the highest incremental cancer risk, chronic hazard quotient, and $PM_{2.5}$ concentration from the Project across all populations and exposure scenarios. A summary of the cumulative impacts at the Project MEI is shown in **Table 3.3-27**. As shown in **Table 3.3-27**, cumulative health risks at the MEI would not exceed the BAAQMD thresholds for cumulative health risks. Therefore, the cumulative impact on the exposure of sensitive receptors to substantial pollutant concentrations resulting from the Project in combination with other probable future projects would not be significant, and the Project's contribution would not be cumulatively considerable.

Table 3.3-27. Summary of Cumulative Health Risk Assessment Results

	BAAQMD Threshold of Significance	Mitigated	
		MEI	*Exceed Threshold?*[1]
Excess Lifetime Cancer Risk (in a million)	100	18 ~~21~~	*No*
Chronic HI	10	0.018 ~~0.022~~	*No*
$PM_{2.5}$ Concentration (µg/m³)	0.8	0.47 ~~0.65~~	*No*

Source: Appendix E: Summary Table Q ~~Table 61~~

Key: HI = hazard index; PM2.5 = particulate matter 2.5 microns or less in diameter; µg/m3 = micrograms per cubic meter; MEI = maximally exposed individual

Notes:

[1] Project unmitigated cumulative health risk also does not exceed the BAAQMD significance thresholds (see Appendix E: Table 61).

Significance Conclusion Summary

The Project's contribution to exposure of sensitive receptors to substantial pollutant concentrations would **not be cumulatively considerable** with the FOCP and other potential future projects, programs, or plans.

Mitigation Measures

No mitigation is required.

*Cumulative Impact AQ-4: Other emissions adversely affecting a substantial number of people (*Not Cumulatively Considerable*)*

Construction of the Project would not have a significant impact from odor emissions. Odors generated by construction of the Project would be temporary in nature and based on odor complaints history. Construction of the Project would not generate objectionable odors affecting a substantial number of people.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction or operation activities overlap within the same timeframe as the construction activities for the Project and are land uses that typically emit odors.

Cumulative Effects of Project with the FOCP

The FOCP would be completed before construction activities for the Project begin; therefore, these two projects would not result in cumulative impacts related to objectionable odors. There would be no cumulative effect.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Construction emissions would disperse rapidly with distance, and as a result, construction and operational projects in close proximity to one another would not result in combined odors above those analyzed. Therefore, cumulative odor impacts from probable future projects, plans, and programs would not result in a cumulatively significant odor impact. The cumulative impact related to odors would not be significant, and the Project's contribution would not be cumulatively considerable.

Significance Conclusion Summary

The Project's contribution to other emissions adversely affecting a substantial number of people would **not be cumulatively considerable** with the FOCP and other probable future projects.

Mitigation Measures

No mitigation is required.

3.4 Biological Resources—Fisheries Resources

This section describes the regulatory and environmental setting for fisheries resources and analyzes the environmental impacts of the Project on fisheries resources, including an evaluation of both construction-related and operation-related impacts, resulting from implementation of the Project.

For post-construction flows, impacts are evaluated in comparison to the:

- "Pre-FERC Order Baseline" – represented by groundwater recharge operations to meet consumer demand and Coyote Creek conditions immediately prior to the 2020 FERC IRRM Order (i.e., prior to the reservoir drawdown to Deadpool and FOCP)
- "Future Baseline," – anticipated future, post-Project "business as usual" Anderson Dam operations without implementing FAHCE or flow regime improvements, after all seismic safety improvements have been implemented, permitting the reservoir to return to maximum storage capacity, including groundwater recharge operations to meet future anticipated consumer demand, and anticipated Coyote Creek conditions in the absence of drawdown, FOCP construction, and Project construction

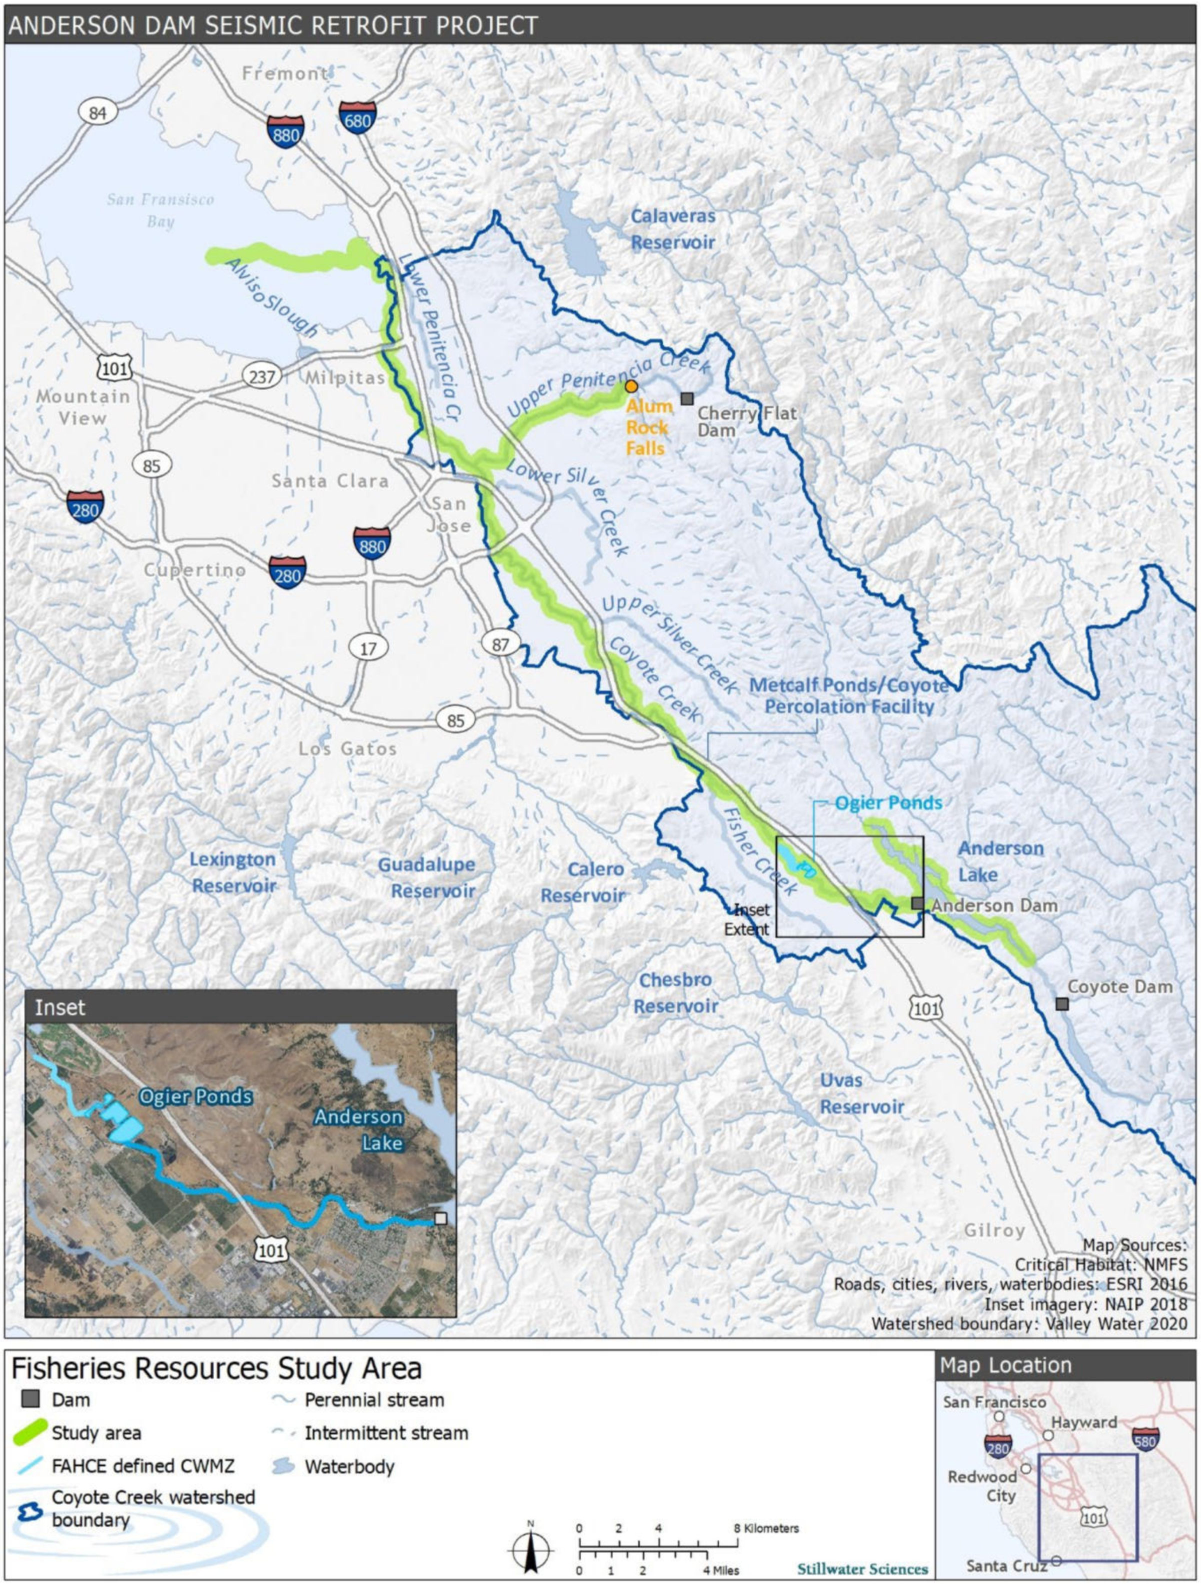
For non-flow related construction phase impacts of Project improvements and facilities to be constructed either an existing conditions baseline based on data available at the time of EIR preparation, or a post-FOCP conditions baseline (if FOCP implementation has changed these existing conditions) is used, which allows for a more accurate prediction of Project impacts. Where resources would be affected by construction phase dewatering and operations, including implementation of the Project Construction Period Reservoir Operations and Drawdown Plan, which describes the two-stage reservoir dewatering plan and construction phase flow related Conservation Measures, effects would be evaluated in comparison to:

- existing conditions, to take into account effects on the existing reservoir drawdown conditions as well as use of imported water releases, chillers and other FOCP avoidance and minimization measures for aquatic resources; and
- the Pre-FERC Order Baseline to evaluate construction phase impacts on aquatic resources in the study area during normal Anderson reservoir and Coyote Creek flow conditions.

The study area used to assess impacts on fisheries resources is defined as the area and immediate vicinity within which all construction-related activities or ground disturbance would occur, as well as other areas whose fisheries would be affected by Project construction and operations. Specifically, the fisheries resources study area comprises:

- Coyote Creek, from the base of Anderson Dam downstream to the tidally inundated portion of lower Coyote Creek
- the waters of San Francisco Bay included in Coyote Creek to the confluence with Alviso Slough
- lands in the immediate vicinity of Anderson Reservoir and Coyote Creek
- Upper Penitencia Creek downstream of Alum Rock Falls (**Figure 3.4-1**)

1 **Figure 3.4-1. Fisheries Resources Study Area**



2

3.4.1 Environmental Setting

This section provides descriptions of the key waterways, stream habitat conditions, and special-status fish species in the study area. To identify occurrence of fisheries resources under the Pre-FERC Order Baseline, Existing Conditions, and Post-FOCP biological conditions for fisheries resources in the study area, as well as the historical context of special-status fish populations, a number of information sources were reviewed, including the following:

- FAHCE *Settlement Agreement* (FAHCE 2003a ~~2003b~~)
- Valley Water Daily WEAP Model Technical Memorandum (SEI and Valley Water 2020)
- Existing and historical hydrologic conditions of Coyote Creek document (Balance Hydrologics 2005)
- Coyote Creek Instream Flow Assessment (Stillwater Sciences 2021)
- Sediment Transport Modeling documents (URS 2020a, 2020b)
- Document describing priority locations for gravel augmentation and large woody debris placement (Balance Hydrologics 2018)
- Documents prepared for Valley Water's evaluation of its DMP (Valley Water 2008a, 2008b, 2012)
- Documents prepared for Valley Water's SMP Update (Valley Water 2011 ~~2011a, 2011b,~~ 2014)
- Santa Clara ~~The~~ Valley Habitat Plan (ICF 2012)
- Data on special-status species occurrences (~~Bousman 2007,~~ CDFW 2008, Shuford and Gardali 2008, California Natural Diversity Data Base [CNDDB] 2018, USFWS 2014)
- Coyote Creek Watershed Fisheries Monitoring, Years 2018-2022 (Valley Water 2019 ~~2019a~~, 2020a, 2021a, 2021b, 2022a)
- Fish Population Sampling in Fall 2014-2020 on Coyote Creek (Leicester and Smith 2014, 2015; Smith~~, 2015,~~ 2016, 2017, 2018, 2019, 2020)
- Fish Assemblage of Anderson Reservoir 2017 and 2019 (Valley Water 2020b)
- Fish Assemblage of Anderson Reservoir 2019 (Valley Water 2020c)
- Coyote Creek Fish Rescue and Relocation 2021 (Valley Water ~~and Stillwater Sciences~~ 2020d, Valley Water 2021c ~~2021h~~)

3.4.1.1 Fisheries Resources and Related Aquatic Habitat

The EIR's assessment of fisheries impacts is an analysis of impacts on "candidate, sensitive, or special-status species," as suggested by *CEQA Guidelines* Appendix G. Special-status aquatic species with the potential to occur in the study area are identified in **Table 3.4-1**, and the seasonal occurrence of each special-status species in the study area by life stage is shown in **Table 3.4-2**.

Table 3.4-1. Special-Status Fish Species Evaluated in the Fisheries Resources Study Area

Name	Scientific Name	Regulatory Status	Potential for Occurrence in the Project Area
Central California coast steelhead	*Oncorhynchus mykiss*	FT; Designated critical habitat	**Present.** Observed in Coyote Creek immediately downstream of the dam, and in tributaries to Coyote Creek, including Upper Penitencia Creek (NMFS 2006, 2009, 2016; Valley Water 2019~~a~~, 2020a, 2021a, 2021b, 2022a). Resident *O. mykiss* upstream of Anderson Dam in Coyote Creek and upstream of Cherry Flat Dam in Upper Penitencia are not considered part of the CCC DPS and are not considered special-status (NMFS 2006). Critical habitat is designated within the study area in Coyote Creek downstream of Anderson dam and within Upper Penitencia Creek downstream of the dam at Cherry Flat reservoir.
Central Valley fall-run Chinook salmon	*Oncorhynchus tshawytscha*	FSC/CSSC; Designated EFH	**Present.** Adult Chinook salmon have been observed as far upstream as Coyote Percolation Dam and were observed migrating upstream (Valley Water 2020a Valley Water 2021d ~~2021c~~). It is reasonable to assume that Chinook salmon can migrate to the base of Anderson Dam. EFH is designated within the study area in Coyote Creek, downstream of Anderson Dam.
Longfin smelt	*Spirinchus thaleichthys*	FC; ST	**Present.** Longfin smelt occur in the lowermost, tidally influenced estuarine reaches of Coyote Creek and Alviso Slough (Valley Water 2013, Otolith Geochemistry & Fish Ecology Laboratory 2021).
Pacific lamprey	*Entosphenus tridentatus*	CSSC	**Present.** Pacific lamprey occur in mainstem Coyote Creek downstream of Anderson Dam and in Upper Penitencia Creek (Buchan and Randall 2003, Valley Water 2020e ~~2020d~~ and 2021e).
Riffle sculpin	*Cottus gulosus*	CSSC	**Present.** Riffle sculpin occur in Upper Penitencia Creek (Valley Water 2020a, Valley Water 2021a).
Sacramento hitch	*Lavinia exilicauda exilicauda*	CSSC	**Present.** Sacramento hitch occur in Coyote Creek downstream of Anderson Reservoir (Leidy 2007, Valley Water 2020a) and in Anderson Reservoir (Leidy 2007).
Southern coastal roach	*Hesperoleucus venustus subditus*	CSSC	**Present.** Southern coastal roach occur in Upper Penitencia Creek and within Coyote Creek downstream of Anderson Dam (Leidy 2007, ~~SCVWA~~ Valley Water 2008a, 2008b, 2020a, 2021a, ~~Valley Water 2020a,~~ 2021f).

Name	Scientific Name	Regulatory Status	Potential for Occurrence in the Project Area
Southern green sturgeon	*Acipenser medirostris*	FT; Designated critical habitat	**Not Observed; Very Low Potential to Occur.** Although green sturgeon have not been documented and are generally not expected to occur in Coyote Creek or Alviso Slough (Otolith Geochemistry & Fish Ecology Laboratory 2021), critical habitat is designated under the ESA within the lowermost, tidally influenced reaches of Coyote Creek and green sturgeon have been detected in the South San Francisco Bay on rare occasions (Crauder et al. 2016, Miller et al. 2020).
White sturgeon	*Acipenser transmontanus*	CSSC	**Present**. White sturgeon occur in Alviso Slough and the tidally influenced portion of Coyote Creek (Otolith Geochemistry & Fish Ecology Laboratory 2021).

Key: Status: Federally Threatened (FT); State Threatened (ST); Federal Candidate (FC); Federal Species of Concern (FSC); California Species of Special Concern (CSSC); Essential Fish Habitat (EFH)

Central California Coast Steelhead

The CCC steelhead (steelhead) distinct population segment (DPS) occurs within the study area and is a federally threatened population. The DPS includes naturally spawned populations of steelhead (and their progeny) residing downstream of long-term impassable barriers, both natural and human-made, in coastal drainages from the Russian River to Aptos Creek, and the drainages of San Francisco and San Padblo Bays, excluding the Sacramento-San Joaquin River Watershed. The CCC steelhead DPS was federally listed as threatened in 1997 (NMFS 2006). The California Coastal Multispecies Recovery Plan was developed in 2016 to provide a framework for the conservation and survival of listed species, including CCC steelhead (NMFS 2016). The most pressing threats to the CCC DPS identified in the Coyote Creek Watershed are loss of floodplain connectivity, flow conditions, and fish passage, as well as water diversion and impoundment (NMFS 2016). The CCC steelhead DPS includes the study area found downstream of long-term impassable barriers within the Coyote Creek mainstem (Anderson Dam) and Upper Penitencia Creek (Cherry Flat Dam; although anadromy is precluded further downstream by a waterfall) (62 Federal Register 159; 71 Federal Register 834).

For ease of communication, CCC steelhead DPS is used interchangeably with “steelhead” throughout this document. The DPS acronym is used in specific regulatory contexts regarding the CCC steelhead DPS, while steelhead is used in the impact analysis and more general discussions regarding steelhead in the fisheries resources study area. The species name abbreviation *O. mykiss* is used when referring to fish within the species that cannot be differentiated between the resident form (i.e., rainbow trout, which is not listed) and anadromous form (which is listed and referred to as steelhead or the DPS). Although there is a regulatory differentiation, in practice, rainbow trout downstream of impassable barriers receive protection under the ESA because they usually cannot be visually differentiated from the anadromous form.

Critical habitat for the CCC steelhead DPS was designated on September 2, 2005 (70 Federal Register 52488 52630). CCC steelhead critical habitat is designated in the fisheries resources study area in Coyote Creek from Anderson Dam to San Francisco Bay, and in Upper Penitencia Creek from the confluence of Coyote Creek and Upper Penitencia Creek to the dam at Cherry Flat Reservoir. A CDFW barrier assessment of Upper Penitencia Creek indicates that anadromous adult access ends at a waterfall located downstream of Cherry Flat Reservoir, just upstream of the confluence with Arroyo Aguague (CDFW 2018a, NMFS 2016).

Steelhead Life History

O. mykiss exhibit broad range of life-history strategies (NMFS 2012), including anadromy, where juveniles [1] rear in freshwater rivers and creeks, smolts [2] migrate to the ocean where they mature to adults, and adults return to freshwater rivers and creeks to spawn, usually after 1 to 3 years in the marine environment. They can also exhibit a resident life history, where rearing, maturing, and spawning all occur within freshwater. Steelhead are broadly categorized into winter and summer migration timing. Winter steelhead are the most widespread life history and the only life history observed in the Coyote Creek Watershed.

[1] In this report juvenile steelhead refers to all pre-smolt juveniles, both young-of-the-year and age 1+/2+, unless indicated separately.
[2] Smolts are juvenile steelhead migrating to the ocean (i.e., smolting) that exhibit silver coloration and have no parr marks.

CCC steelhead generally enter natal spawning streams as sexually mature adults from December through April. Upstream migration is thought to be opportunistic during precipitation-driven high-flow events. Steelhead spawn in late winter or spring (Shapovalov and Taft 1954, Meehan and Bjornn 1991, Behnke 1992, Moyle et al. 2008). Spawning occurs primarily from January through March but may begin as early as late December and may extend through April (Hallock et al. 1961, Moyle 2002). Individual steelhead may spawn more than once in their lifetime (iteroparity), returning to the ocean between each spawning migration.

Once adults reach the spawning habitat, the adults dig redds (gravel nests) and commence spawning activity. The eggs incubate in the redds for three weeks to two months, depending on water temperature (NMFS 2013). After they hatch, the alevin (larval fish with attached yolk sacs) remain in the redds until the yolk sacs have been absorbed. Based on the conditions within Coyote Creek, the incubation period is expected to occur between December and May (Valley Water 2021b). The fry (young juveniles) then move into the water column to rear. Based on *O. mykiss* captured and measured in the neighboring Guadalupe River Watershed, fry are expected to be rearing in Coyote Creek between March and May (Valley Water 2023a ~~2019b~~).

Upon emerging from the gravel, fry rear in edgewater habitats and move gradually into pools (smooth surface and deep, low-velocity water) and riffles (shallow, where water flows over coarse streambed particles and create surface turbulence) as they grow larger. Juvenile steelhead typically rear in freshwater for 1 to 3 years before migrating to the ocean as smolts (Shapovalov and Taft 1954, NMFS 2013). The duration of time juvenile steelhead spend in freshwater appears to be related to growth rate, with larger, faster-growing juveniles smolting earlier (Peven et al. 1994). Steelhead in areas with warm water temperatures, where food availability is high and other habitat conditions are suitable, may require a shorter period in freshwater before smolting, while steelhead in colder, more northern, and inland streams may require a longer time period (Sloat and Reeves 2014). Juvenile migration to the ocean generally occurs from February through May (see **Table 3.4-2** for a summary of the life-history timing for steelhead in the Coyote Creek Watershed).

Steelhead Habitat Requirements

Steelhead have habitat requirements for each life-history stage: spawning, incubation, fry rearing, and juvenile rearing, as well as conditions for adult and smolt migration that underlie both the qualitative and quantitative impact analyses of instream flows on steelhead habitat. This section summarizes steelhead habitat requirements from literature reviews conducted through the FAHCE process and identifies thresholds or suitability curves that are later used in the methods for modeling steelhead habitat changes under the Project compared to baseline conditions. Further details on how these habitat requirements were incorporated into the habitat modeling for the following fisheries resources impacts analysis can be found in the Fisheries Habitat Availability Estimation Methodology (Valley Water 2023a ~~2019b~~), the Section 3.4.3 *Methodology and Approach to Impact Analysis*, and Appendix F. The Fisheries Habitat Availability Estimation Methodology is included as Appendix N of the FAHCE Final EIR (Valley Water 2023a) ~~2023b~~.

To migrate upstream, adult steelhead require water depths greater than 0.5 feet (Thompson 1972, Bell 1991), and water velocities less than or equal to 8 feet per second (ft/s) (Thompson 1972, Bell 1991). While upstream migrating adult steelhead require a depth greater than 0.5 feet for passage, a review of available literature indicates a water depth of 0.7 feet or greater is more suitable for adult steelhead passage (e.g., Thompson 1972, SWRCB 2007, CDFW 2013, SWRCB 2014, Holmes et al. 2015) and a water depth of 0.7 feet or greater has recently been applied as a depth criterion for adult steelhead migration on the California coast (CDFW 2013, SWRCB 2014). A thalweg water depth criterion of 0.7 feet or greater was selected in coordination with the FAHCE TWG for assessing adult steelhead upstream passage based on the results of the literature review (Valley Water 2023a ~~2019b~~) and was used in the modeling methods for upstream passage (Section 3.4.3; Appendix F).

Adult steelhead upstream passage is also related to water temperature. In a review of various water temperature studies on anadromous salmonids summarized in McCullough et al. (2001), USEPA (2003) found that the cumulative stresses of water temperatures consistently greater than 62.6–64.4 °F (17–18 °C) resulted in an overall reduction in migration fitness. Telemetry research on summer-run steelhead in the Columbia River basin has identified approximately 66 °F (approximately 19 °C) as an important behavioral thermal threshold, where adults have been observed to seek out thermal refugia during their upstream migration (Keefer et al. 2009, as cited in Keefer et al. 2018). Thermal migration barriers for adult immigration have frequently been reported for salmonids, including steelhead, when water temperatures reach approximately 70 °F (approximately 21 °C) (McCullough et al. 2001). Bratovich et al. (2012) identified an adult steelhead migration upper optimal water temperature of 64 °F (17.8 °C) and an upper tolerable water temperature of 68 °F (20.0 °C), along with an adult steelhead holding upper optimal and upper tolerable water temperatures between 61–65 °F (16.1–18.3 °C), respectively, from a review of literature on adult steelhead migration and holding water temperatures, including McCullough et al. (2001), NMFS (2000a, 2002 ~~2001~~), Richter and Kolmes (2005), SWRCB (2003), USBR (1997 [as cited in Bratovich et al. 2012], 2004 ~~2003~~), and USFWS (2001 ~~1995~~). Suitable water temperatures for adult steelhead migration were typically higher than adult steelhead holding, primarily due to increased duration of exposure to water temperature during adult holding relative to migration. A water temperature binary criterion of 65 °F (18.3 °C) was selected for adult steelhead upstream passage, with water temperature considered suitable when it was less than or equal to 65 °F (18.3 °C) and unsuitable when it was greater than 65 °F (18.3 °C) since the upper tolerable water temperature for adult steelhead holding would be limiting for adult steelhead upstream passage (Valley Water 2023a ~~2019b~~).

Steelhead select spawning sites with gravel substrate and sufficient water velocity to maintain circulation through the gravel, providing a clean, well-oxygenated environment for incubating eggs. The preferred flow velocity for spawning is generally in the range of 1 to 3 ft/s (Raleigh et al. 1984). Literature from watersheds less than 500 mi^2 (Snider et al. 1995, USFWS 2007), as well as from the Trinity River (Hampton 1997) and Bovee (1978) were compiled and used to develop continuous steelhead spawning depth and velocity suitability curves based on the principles presented in Bovee et al. (1998) (Valley Water 2023a ~~2019b~~). Suitability curves were generally irregularly shaped parabolas due to the variations in depth and velocity suitability reported in literature. Water depths greater than 0.33 feet and less than 3.40 feet were considered suitable for steelhead spawning, with an optimal water depth of 1.24 feet. Water velocities greater than 0.68 ft/s and less than 3.88 ft/s were considered suitable for steelhead spawning, with an optimal water velocity of 1.68 ft/s. Please refer to (Valley Water 2023a ~~2019b~~) for the specific suitability curves. The preferred gravel substrate for spawning steelhead is in the range of 0.5 to 4 inches in diameter (Bjornn and Reiser 1991, NMFS 2016). In addition to substrate size, the percentage of fine sediment (in terms of cobble embeddedness) is also a primary determinant of spawning and incubation habitat quality. For example, Bjornn and Reiser (1991) present data showing that survival of steelhead (and Chinook salmon) embryos generally begins to decline as the percentage of fine sediment in the redd increases above 25 percent.

Water depth is generally considered sufficient for steelhead embryo incubation provided eggs are kept moist during incubation and redds are submerged when fry begin to hatch and emerge (Raleigh et al. 1984). SWRCB (2007) assumed that the minimum depth for embryo incubation is approximately 0.1 foot above the bed surface, so a water depth binary criterion of 0.1 foot was selected for steelhead embryo incubation, with water depths considered suitable when it was 0.1 foot or greater and unsuitable when it was less than 0.1 foot. If the 0.1-foot water depth criterion was not met for one day of the forecasted incubation period, embryo incubation during that period was not considered successful (Valley Water 2023a ~~2019b~~).

Water temperature is also important for steelhead spawning and embryo incubation, with optimal steelhead spawning water temperatures reported to range from 39–52 °F (4–11 °C) (McEwan and Jackson ~~Nelson~~ 1996 ~~1991~~). USEPA (2003) found that good survival of embryos occurs at constant water temperatures of about 39.2 to 53.6 °F (4 to 12 °C) from a review of various water temperature studies on anadromous salmonid embryos summarized in McCullough et al. (2001). Water temperature-related embryo survival is generally believed to be maximized at approximately 45–50 °F (7–10 °C), with some increase in mortality below and above this range (Myrick and Cech 2004). Most of the studies of *O. mykiss* embryo incubation conducted at or near 54.0 °F (12.2 °C) report high survival and normal development (Kamler and Kato 1983 as cited in Bratovich et al. 2012; Redding and Schreck 1979, Rombough 1988). Embryonic mortality increases sharply, and development is slowed at incubation temperatures greater than or equal to 57.0 °F (13.9 °C) (Velsen 1987, Rombough 1988). Bratovich et al. (2012) identified an upper optimal water temperature index value of 54 °F (12.2 °C) and an upper tolerable index value of 57 °F (13.9 °C) for steelhead embryo incubation based on a review of various water temperature studies, including NMFS (2000a, ~~2001,~~ 2002), USFWS (2001 ~~1995~~), USBR (1997 [as cited in Bratovich et al. 2012]), SWRCB (2003), Rombough (1988), Kamler and Kato (1983) as cited in Bratovich et al. 2012, Redding and Schreck (1979), USEPA (2001), Humpesch (1985), and McCullough et al. (2001). As such, an upper optimal water temperature binary criterion of 54 °F (12.2 °C) was selected for the steelhead spawning and incubation life stage based on an overall assessment of the various water temperature ranges reported to characterize the highest water temperature that could support high embryo survival in the literature and data review, with water temperature considered suitable when it was less than or equal to 54 °F (12.2 °C) and unsuitable when it was greater than 54 °F (12.2 °C). An upper tolerable water temperature binary criterion of 57 °F (13.9 °C) also was also selected for the steelhead spawning and incubation life-stage to represent the highest water temperature before embryonic mortality increases sharply and development becomes retarded slowed based on a synthesis of the water temperature ranges for embryo development in the reviewed literature and data, with water temperature considered suitable when it was less than or equal to 57 °F (13.9 °C) and unsuitable when it was greater than 57 °F (13.9 °C) (Valley Water 2023a ~~2019b~~).

After fry emerge from the gravel, they inhabit low-velocity areas along the stream margins. As they feed and grow, they gradually move to deeper and faster water. Juvenile salmonids prefer well-shaded pools at least 3.28 feet deep with dense overhead cover, or abundant submerged cover, composed of undercut banks, logs, roots, and other woody debris (NMFS 2016). Due to the life stage-specific preferences, separate depth and velocity suitability curves were identified and applied for fry and juveniles according to the same method applied for steelhead spawning, but including data from Holmes et al. (2014), Hampton (1997), Snider et al. (1995), and Bovee (1978) along with NMFS and Kier Associates (2008), Raleigh et al. (1984), Bustard and Narver (1975) for juvenile *O. mykiss* depth preferences (Valley Water 2023a ~~2019b~~). Water depths greater than 0 feet and less than 4.25 feet are considered suitable for steelhead fry rearing, with an optimal water depth of 0.63 feet (Valley Water 2023a ~~2019b~~). Water velocities greater than 0 ft/s and less than 2.81 ft/s are considered suitable for steelhead fry rearing, with an optimal water velocity of 0.41 ft/s. Water depths greater than 0.22 feet and less than 5.70 feet are considered suitable for steelhead juvenile rearing, with optimal water depths ranging from 1.49 to 3.00 feet. Water velocities greater than 0.05 ft/s and less than 4.45 ft/s are considered suitable for steelhead juvenile rearing, with an optimal water velocity of 1.14 ft/s (Valley Water 2023a ~~2019b~~).

Instream cover also is an important habitat component for juvenile *O. mykiss*, providing refuge from high-flow velocities and predation (Shirvell 1990, Meehan and Bjornn 1991). While cover provides refuge from high flows during winter and spring, steelhead in central California streams remain active during winter based on high growth rates (Sogard et al. 2009). Cover is particularly important in areas where water depths are shallow, which is the case for some stream reaches during summer low-flow conditions. For example, yearling and older *O. mykiss* (less than 4 inches) will reportedly abandon areas that are less than 6 inches deep unless there is abundant cover (Cramer and Ackerman 2009). However, steelhead tend to use riffles and other habitats not strongly associated with cover during summer rearing, more so than other salmonids (Shapovalov and Taft 1954). Increased prey availability in these habitats can offset the increased metabolic demands of higher water temperatures (Smith and Li 1983).

Water temperature and food availability are also critical habitat factors for rearing fry and juveniles. Water temperature has a strong influence on each steelhead life-history stage, as well as metabolism and growth rates for fry and juveniles (Sullivan et al. 2000). Food availability and consumption rate are critical factors for *O. mykiss* as the mediation of water temperature increases (Railsback and Kenneth 1999). When additional food is available, juvenile *O. mykiss* can also increase feeding to meet increased metabolic demands imposed by above-optimal temperatures, and growth rates can be higher under warmer conditions (Wurtsbaugh and Davis 1977, Hayes et al. 2008).

The reported preferred and tolerable water temperatures for juvenile steelhead can be highly variable, associated with variable acclimation temperatures, local adaptation, food availability, and other site-specific conditions. In general, water temperatures less than 68 °F (20 °C) are considered suitable for rearing steelhead (Hayes et al. 2008). While the preferred water temperatures for fry and juvenile steelhead across geographic regions have been reported to range from about 45–65 °F (7.2–18.3 °C) (Adams et al. 1975, Myrick and Cech 2001, Rich 1987), or less than 55 °F (12.8 °C) (USEPA 2003; McCullough et al. 2001), juvenile CCC steelhead have been observed in streams with temperatures as high as 75–79 °F (24–26 °C) (Hayes et al. 2008, Kubicek and Price 1976) with numerous reports citing juveniles present at temperatures of approximately 72 °F (22 °C) (NCRCD 2014; Sonoma County Water Agency [SCWA] 2003; Smith 2018). The upper incipient lethal temperature for juvenile rainbow trout is reported to be 75–79 °F (Sullivan et al. 2000, McCullough et al. 2001). However, juvenile steelhead in southern California have been observed at 88.7 °F (31.5 °C) (Sloat and Osterback 2012 ~~2013~~); juvenile steelhead have been observed to persist at summer water temperatures of up to approximately 82 °F (28 °C) or even 86 °F (30 °C) in eastern Oregon streams (Li et al. 1994); and Myrick and Cech (2000; 2005) reported critical thermal maxima ranging from approximately 86–90 °F (30–

32 °C) for some strains of *O. mykiss* (rainbow trout) acclimated to water temperatures of 68–77 °F (20–25 °C). Observations of juvenile CCC steelhead from approximately 72 °F (22 °C) to as high as 79 °F (26.1 °C) align with those reported from controlled swim tunnel respirometry studies that showed juvenile *O. mykiss* from the CCC steelhead population could maintain 95 percent of their aerobic scope, the difference between maximum and resting oxygen consumption, at temperatures as high as 76.3 °F (24.6 °C) (Verhille et al. 2016). Taken together, these studies provide evidence that steelhead in central California can tolerate temperatures greater than 75.2 °F (24 °C), but intraspecific thermal physiologies occur and some populations have higher or lower thermal tolerance (Myrick & Cech 2000, 2001; Beakes et al. 2010; Chen et al. 2015). The variable temperature tolerance of juvenile steelhead across their range provides flexibility during extreme water temperature conditions; however, tradeoffs exist as growth rates decline, vulnerability to disease increases, and temperature sensitive physiological mechanisms such as smoltification are impacted (Zillig et al. 2021).

Water temperature can also influence steelhead indirectly by altering ecological interactions (e.g., competition and predation) and food availability. For example, in some watersheds, warm water temperatures support and provide a competitive advantage for aquatic non-native species such as largemouth bass (*Micropterus salmoides*) (Rahel and Olden 2008). Aquatic non-native species have been documented to prey on juvenile steelhead and compete for habitat and food resources (Carey et al. 2011, Thompson et al. 2012).

A literature review of water temperature effects on fry and juvenile *O. mykiss*, including many of the citations discussed above and other studies evaluating suitable water temperatures for fry and juvenile *O. mykiss*, was conducted to develop a continuous fry and juvenile rearing water temperature suitability curve (Valley Water 2023a ~~2019b~~). A fry and juvenile rearing water temperature suitability curve was constructed by overlaying two sets of binary water temperature criteria pertaining to “optimal growth” and “survival” based on the principles of a generic water temperature suitability curve presented in Bovee et al. (1998). A synthesis of the water temperature ranges in the reviewed literature identified an “optimal growth” water temperature range for fry and juvenile steelhead as 50–65 °F (10–18.3 °C), with the lower limit based on USEPA (2003) and the upper limit based on (1) the water temperatures associated with optimal growth at various rations in the North Santiam River and in the lower American River (see Myrick and Cech [2001]); (2) the upper optimal water temperature identified by Bratovich et al. (2012) for juvenile steelhead rearing in the Central Valley; and (3) NMFS (2016). A synthesis of the water temperature ranges in the reviewed literature identified a “survival” water temperature range as 36–75 °F (2–24 °C), with the lower limit based on the higher thermal minimum identified for juvenile rainbow trout across studies presented by Myrick and Cech (2001) and the upper limit based on the lower end of the upper incipient lethal temperature range reported by Sullivan et al. (2000) and McCullough et al. (2001) for rainbow trout. The water temperature ranges identified above synthesized the steelhead fry and juvenile water temperature tolerances from multiple literature and data sources to best characterize the range of thermal tolerances of steelhead in Coyote Creek, but individual studies may identify slightly different “optimal,” “optimal growth,” “tolerable,” or “survival” water temperature ranges depending on the steelhead population studied (e.g., coastal or Central Valley), method of assessment (e.g., observation in field versus lab experiments), or the statistical time period considered (e.g., daily average versus weekly average). A continuous suitability curve was developed from these temperature criteria by fitting a third order polynomial function to the lower survivable temperature value (36 °F [2 °C]), lower optimal growth temperature value (50 °F [10 °C]), upper optimal growth temperature value (65 °F [18.3 °C]), and the upper survivable temperature value (75 °F [24 °C]) to create a biologically realistic variation in the water temperature suitability. Valley Water 2023a ~~2019b~~ provides further details, including a graph of the water temperature suitability curve. The water temperature suitability curve for steelhead fry and juvenile rearing was used in the WEAP model (SEI and Valley Water 2020) to estimate how water temperature variations altered fry or juvenile rearing habitat availability, so the EIR references these criteria when discussing the effects of water temperature on fry or juvenile rearing steelhead to be consistent.

The timing when juvenile steelhead begin their downstream migration may be affected by various environmental factors, including flow, water temperature, chemical factors (e.g., oxygen), turbidity, light, and food availability (Shapovalov and Taft 1954, Friesen et al. 2007, Giorgi et al. 1997, Kock et al. 2015, Gregory and Levings 1998). Flow must be sufficient to provide a water depth of at least 0.4 feet for juvenile steelhead downstream migration (CDFW 2013), so a thalweg water depth criterion of 0.4 feet or greater was selected for assessing juvenile steelhead downstream passage opportunities (Valley Water 2023a ~~2019b~~). The specific duration of time juvenile steelhead spend in freshwater before smolting appears to be related to growth rate, with larger, faster-growing juveniles smolting earlier (Peven et al. 1994). Steelhead in areas with warm water temperatures, where food availability is high and other habitat conditions are suitable, may require a shorter period in freshwater before smolting, while steelhead in colder, more northern, and inland streams may require a longer time period (Sloat and Reeves 2014). Most literature on water temperature effects on steelhead smolting suggest that water temperatures less than 52 °F (11 °C) are required for successful smoltification to occur (Adams et al. 1975, Myrick and Cech 2001, Rich 1987). Myrick and Cech (2001) suggest that water temperatures between 43–50 °F (6.1–10 °C) are the "physiologically optimal" temperatures required during the parr-smolt transformation and necessary to maximize saltwater survival. Zedonis and Newcomb (1997) reported any increase in water temperature above 59°F (15°C) during the smolt outmigration period would result in decreased smolting tendencies. NMFS (2016) stated that suitable water temperatures during the parr to smolt transformation and outmigration periods for steelhead range between approximately 50–63 °F (10–17 °C), with water temperatures less than 59 °F (15 °C) considered to be most optimal. However, SCWA (2016) documented steelhead smolts migrating downstream while mean daily temperature (MDT) was consistently above 59 °F (15 °C) and 7-day average of daily maximum (7DADM) was above 68 °F (20 °C). Similarly, downstream migrant smolt data from Valley Water collected in the late 1990s and early 2000s showed steelhead smolt migration occurs consistently while MDT exceeds 59 °F (15 °C) and 7DADM is above 68 °F (20 °C). In Coyote Creek specifically, 174 steelhead smolts were captured when MDT was higher than 59 °F (15 °C) and 17 steelhead smolts were captured during the period when 7DADM was above 68 °F (20 °C). While there is data to indicate smolting occurs above 59 °F (15 °C), an upper tolerable water temperature binary criterion of 59 °F (15 °C) was selected for juvenile steelhead downstream migration based on an overall assessment of the various water temperature ranges reported, with water temperature considered suitable for juvenile steelhead downstream migration when it was less than or equal to 59 °F (15 °C) and unsuitable when it was greater than 59 °F (15 °C) (Valley Water 2023a ~~2019b~~).

The discussion above summarizes the habitat requirements of steelhead described in literature and data, but it should be noted that the majority of available data used for evaluating temperature tolerance in McCollough et al. (2001) were from steelhead populations in the U.S. Pacific Northwest. Additional studies published after McCollough et al. (2001) have provided evidence for population-specific thermal tolerances for steelhead (Myrick and Cech 2001, 2005;

Sloat and Osterback 2012 ~~2013~~; Verhille et al. 2016; Zillig et al. 2021), with populations at the steelhead southern range having higher temperature tolerance compared with more northern populations.

In addition, adequate concentrations of DO in fresh water are critical for the survival of all life stages of steelhead (Carter 2008). The Basin Plan indicates that the DO objectives for Coyote Creek waters designated as COLD have minimum instantaneous DO of 7 milligrams per liter (mg/L). The median DO concentration for any three consecutive months shall not be less than 80 percent of the DO content at saturation (San Francisco Bay RWQCB 2019). ~~exposure of 3.5 days at DO concentrations of 3 mg/L or lower as the threshold at which mortality begins (USEPA 1986)~~

Critical habitat for the CCC steelhead DPS was designated on September 2, 2005. The range of critical habitat for this species includes the Russian River south to Aptos Creek and includes the San Francisco Bay tributaries. Within the fisheries resources study area, critical habitat for Central California coast steelhead habitat is designated in Coyote Creek from Anderson Dam to San Francisco Bay, in Upper Penitencia Creek from the confluence of Coyote Creek and Upper Penitencia Creek to Cherry Flat Reservoir, and in Arroyo Aguague Creek from its confluence with Upper Penitencia Creek to a waterfall that presents a barrier to anadromy approximately one mile upstream.

The Physical and Biological Features identified by NMFS specific to CCC steelhead critical habitat in the fisheries resources study area comprise freshwater spawning and rearing sites with suitable water quality and quantity, and migration corridors without obstructions for juvenile and adult life stages. Spawning sites require substrate suitable for successful spawning. Migration corridors must provide velocity refugia so migrating fish arrive at either the ocean or the spawning grounds successfully and with the necessary energy stores to complete the life-history stage. Based on the CCC DPS recovery plan (NMFS 2016), there are 1,484 miles of critical habitat in the DPS, of which 49 miles (3.3 percent of critical habitat) are within the study area.

Steelhead Occurrence in the Fisheries Resources Study Area

Coyote Creek historically and currently supports an anadromous run of steelhead. Historical information on steelhead in Coyote Creek before the construction of Coyote and Anderson Dams is limited. Descriptions of historical habitat conditions within the Coyote Creek watershed and a report documenting steelhead occurrences provides general evidence of where *O. mykiss* likely occurred (Leidy 2005a, San Francisco Estuary Institute [SFEI] 2006). In the upper Coyote Creek watershed, perennial shaded reaches, such as San Felipe Creek, likely provided high quality habitat for both resident and anadromous *O. mykiss* (SFEI 2006). Additionally, within the present-day FCWMZ, between the dam and Ogier Ponds, there was a mix of sycamore alluvial woodland, with 'occasional short reaches of continuous riparian forest' including cottonwoods and willows (SFEI 2006). Coyote Creek historically transitioned downstream from present-day Anderson Dam from a perennial to intermittent creek, and from an oak-dominant to sycamore-dominant plant community. It was also a meandering and narrower channel directly downstream of Anderson Dam before braiding in downstream segments (SFEI 2006). The present-day FCWMZ has comparatively higher riparian tree cover compared to downstream reaches (SFEI 2006). SFEI (2006) indicates that these sycamore alluvial woodland reaches, characterized by shallow, braided channels and variable flow, provide a unique habitat beneficial to native species, including fish (SFEI 2006). ~~within the present-day FCWMZ, Coyote~~

~~Creek historically was a perennial reach with a dense riparian canopy, presumably supporting *O. mykiss* (SFEI 2006).~~ Snyder (1905, as cited in Leidy et al. 2005a) described the occurrence of *O. mykiss* in Coyote Creek in two locations in 1898, upstream of the mouth to San Francisco Bay and in the lower portion of the stream near present-day San Jose. Downstream of the FCWMZ near present-day Cottonwood Lake, Coyote Creek became intermittent and braided with limited riparian cover, suggesting the fish observed by Snyder in 1898 were migrants and not rearing within that habitat (SFEI 2006). Leidy et al. (2005a) describe tributaries downstream of Anderson Dam as generally being "lightly used" as steelhead habitat, based mostly on the reports of Skinner (1962). Penitencia Creek was diverted in 1852 into Coyote Creek, establishing a new corridor for steelhead to access high quality habitat within Upper Penitencia Creek (SFEI 2006). Prior to the diversion of Penitencia Creek, Upper Penitencia Creek was likely an intermittent stream with rare, if any occurrence, of anadromous salmonids (SFEI 2006). By the 1960s, Upper Penitencia Creek was noted as having a uniquely productive *O. mykiss* population among lower Coyote Creek tributaries (Leidy et al. 2005a).

During the Pre-FERC Order Baseline Condition, as part of Valley Water's early implementation of FAHCE, Valley Water initiated several annual monitoring activities to assess *O. mykiss* in Coyote Creek. FAHCE monitoring efforts began in 2018 and include fall juvenile rearing monitoring, stream temperature monitoring, adult escapement monitoring using the Vaki Riverwatcher system (Vaki), and migration monitoring using PIT tags. Combined, these methods provide key information on the occurrence of *O. mykiss* within the Study Area.

O. mykiss have been observed throughout the mainstem of Coyote Creek and Upper Penitencia Creek, with the largest and most consistent abundance in the mainstem of Coyote Creek in the reach between Anderson Dam and Ogier Ponds (FCWMZ), and Upper Penitencia Creek (Valley Water 2008a, 2008b ~~2008~~; Leicester and Smith 2014; Smith 2016, 2017; Valley Water 2019 ~~2019a~~; ~~Valley Water and Stillwater Sciences 2020~~ Valley Water 2020d).

During existing conditions, *O. mykiss* have been captured in the FCWMZ during FOCP surveys and fish rescue and relocation efforts 2020 through 2023. Pursuant to the emergency Section 7 consultation for FOCP, fish rescue and relocation efforts were conducted in 2020 and 2021 within the FCWMZ. In 2020, rescued *O. mykiss* were relocated to Upper Penitencia Creek and in 2021, rescued *O. mykiss* greater than 4 inches (100 mm) were moved to the downstream mainstem of Coyote Creek at the confluence with Upper Penitencia Creek, while fish less than 4 inches were left in place. During surveys and fish rescues, over 300 *O. mykiss* were captured and a portion of them tagged with PIT tags in 2018-2022 (~~Valley Water and Stillwater Sciences 2020~~;Valley Water 2020d; Valley Water 2021a, 2021b, and 2022a). Many of these fish were juveniles, showing that *O. mykiss* reproduced in the FCWMZ, even during drought conditions and during FOCP. In 2022, rearing monitoring was conducted but *O. mykiss* were left in place in the FCWMZ and not relocated in consultation with resource agencies and the Technical Working Group as conditions within Coyote Creek were the most suitable.

However, adult steelhead are very rare within the FCWMZ and upper portions of the study area. No adult steelhead were documented migrating upstream or downstream on a Vaki Riverwatcher at the Coyote Percolation Dam from 2018 to 2022 (Valley Water 2019 ~~2019a~~, 2020a, 2021a, 2021b, 2022a). There were times when steelhead could have passed but avoided detection (e.g., times when turbidity is too high for the equipment to function, or a power outage caused the computer to shut down) but no steelhead redds were observed during 2020, 2021, or 2022 redd survey efforts following times when the Vaki was not functioning (Valley

Water 2021a, 2021b, and 2022a). Nevertheless large *O. mykiss* have been documented downstream of the dam during rearing studies and anecdotally from anglers.

In the Pre-FERC Order time period, including immediately prior to issuance of the FERC Order the fall of 2019, Valley Water conducted multi-pass depletion backpack electrofishing at four stations in Upper Penitencia Creek between Piedmont Road overcrossing and upstream of Alum Rock Park. *O. mykiss* were detected in the two upstream-most stations (n=63, Valley Water 2020a).

Following implementation of the FERC Order in August 2020, Valley Water conducted electrofishing at five stations in Upper Penitencia Creek. *O. mykiss* were detected in the four upstream-most stations, including a station that was not sampled in 2019 (n=15, Valley Water 2021a). Following the monitoring effort in 2020, Valley Water conducted a fish rescue pursuant to the Fish Rescue and Relocation Plan and 74 *O. mykiss* were rescued from the FCWMZ in Coyote Creek and relocated to Upper Penitencia Creek. However, in the fall of 2021 and 2022, Valley Water detected no *O. mykiss* during rearing monitoring surveys in Upper Penitencia Creek (Valley Water 2022a, 2023), presumably due to dry back and reduced flow from extreme drought conditions. During Pre-FERC Order and existing conditions, *O. mykiss* are not actively monitored downstream of the Coyote Percolation Dam and through the areas of tidal influence so no data are available for occurrence in this reach; however, given that *O. mykiss* are found upstream and the reach, can be intermittent, and lacks suitable spawning and rearing habitat it is likely that this reach is used as a migration corridor. Over time, ongoing PIT tag and Vaki monitoring would shed light on *O. mykiss* migration through the reach downstream of the Coyote Percolation Dam.

Central Valley Fall-Run Chinook Salmon

Central Valley fall-run and late fall-run Chinook salmon (Chinook salmon) occur within the study area and are considered by NMFS to be the same evolutionarily significant unit (ESU) (64 Federal Register 50394). NMFS determined that listing the Central Valley fall-run Chinook salmon ESU as threatened was not warranted (64 Federal Register 50394), but subsequently classified Central Valley fall-run Chinook salmon as a species of concern because of specific risk factors, including population size and hatchery influence (69 Federal Register 19975). Species of concern are not formally listed under the ESA. Because the Central Valley fall-run Chinook salmon ESU is not listed as federally endangered or threatened, critical habitat has not been designated for this species, but EFH is designated in the study area in Coyote Creek downstream of Anderson Dam. CDFW classifies Central Valley fall-run Chinook salmon as a Species of Special Concern. However, while CDFW indicates that the species is found within Central Valley rivers and streams, their range maps do not include Santa Clara County (CDFW 2021) Chinook salmon are included in the FAHCE Settlement Agreement. Henceforth, Chinook salmon that occur in the study area incorporating both fall-run and late fall-run will just be referred to as "Chinook salmon."

Chinook Life History

Central Valley fall-run Chinook salmon adult immigration is reported to occur between August and December (FAHCE ~~2003a,~~ 2003b; Fukushima and Lesh 1998; Leidy 2007; Moyle 2002; Valley Water 2021b). However, based on monitoring of adult Chinook salmon migrating upstream in the adjacent Guadalupe River Watershed, the immigration period was observed between October and January in the neighboring watershed (see Valley Water ~~water~~ 2002 and Nishijima et al. 2009). Based on a review of available data and literature, and because adult Chinook salmon have been observed migrating upstream into January in the adjacent Guadalupe River Watershed, mid-October through January was selected as the evaluation period for fall-run Chinook salmon adult immigration in the fisheries resources study area (Valley Water 2023a ~~2019b~~).

Literature suggests that Central Valley fall-run Chinook salmon adults spawn from the fall through mid-winter. The FAHCE limiting factors analyses (Valley Water 2000) utilized a time period for Chinook salmon adult spawning of October through February, while the FAHCE (2003a) Summary Report identified a time period of mid-October through December. Generally, fall-run Chinook salmon spawn from October through December, but because adult Chinook salmon have been observed migrating upstream into January in the adjacent Guadalupe River Watershed (Nishijima et al. 2009), a spawning time period of mid-October through January was selected for evaluation purposes.

Laboratory experiments in British Columbia (Beacham et al. 1989) found that the average incubation duration of Chinook salmon eggs to fry emergence was 77 days at 53.5 °F (12 °C) (consistent with water temperatures during the winter in the study area during Pre-FERC Order and existing conditions), indicating that Chinook salmon embryos spawned in January would reach the fry emergence stage by the end of March. Therefore, it is assumed that embryo incubation may extend through March.

Juvenile Chinook salmon emergence and rearing can occur from about January through June (Valley Water 2000, 2023 ~~2019b~~; FAHCE 2003b ~~2003a~~). However, based on juvenile outmigration surveys conducted in Coyote Creek and the Guadalupe River (Valley Water 2002, unpubl. data), fry-sized juveniles (i.e., less than 50 millimeter [mm] fork length [FL]) would be present in Coyote Creek from January through April. Fall-run Chinook salmon generally outmigrate from Central Valley rivers as young-of-the-year (Kimmerer and Brown 2006). In Coyote Creek juvenile Chinook salmon outmigration has been observed through the end of April with downstream movement coinciding with precipitation events (Valley Water 2000, 2002; FAHCE 2003b ~~2003a~~). While outmigration can extend into June for other regions of the stock, Chinook salmon are not expected to outmigrate during the months of May and June in Coyote Creek, due to the limited precipitation amounts characteristic of Santa Clara County during those months as well as dewatering the reservoir in April that will help promote outmigration of juveniles.

Chinook Habitat Requirements

Chinook salmon have habitat requirements for each life-history stage: adult migration, spawning, incubation, fry rearing, juvenile rearing, as well as conditions for smolt migration.

Adult Chinook salmon require flows of adequate depth to successfully migrate upstream in freshwater river systems. A literature review indicated a thalweg water depth of 0.9 feet or greater was a suitable water depth for adult Chinook salmon passage, and this criterion has been applied as a water depth criterion for adult Chinook salmon on the California coast (Thompson 1972; SWRCB 2007; CDFW 2013; SWRCB 2014). Based on the results of the literature review, a thalweg water depth criterion of 0.9 feet or greater was selected in coordination with the FAHCE Technical Working Group for assessing adult Chinook salmon upstream passage (Valley Water 2023a ~~2019b~~).

Adult Chinook salmon upstream passage is also related to water temperature. In a review of various water temperature studies on anadromous salmonids summarized in McCullough et al. (2001), USEPA (2003) found that an overall reduction in migration fitness attributable to cumulative stresses occurred at constant water temperatures greater than 62.6–64.4 °F (17–18 °C). Bratovich et al. (2012) identified an adult Chinook salmon migration upper optimal water temperature of 64 °F (17.8 °C) and an upper tolerable water temperature of 68 °F (20.0 °C), along with an adult Chinook salmon holding upper optimal and upper tolerable water temperatures between 61–65 °F (16.1–18.3 °C), respectively, from a review of literature on adult Chinook salmon migration and holding water temperatures, including Berman (1990), Marine (1992), NMFS (1997 ~~1997a~~, 2000a), McCullough (1999), McCullough et al. (2001), Strange (2010), Ward et al. (2004), Ward and Kier (1999), and USFWS (2001 ~~1995~~). Telemetry studies of adult fall-run Chinook salmon in the Columbia River reported migration rates slowed significantly when water temperatures were greater than about 68 °F (20 °C) due to temporary use of tributaries as thermal refugia (Goniea et al. 2006). Thermal migration barriers have frequently been reported for adult salmonid upstream migration, including Chinook salmon (McCullough et al. 2001) and that was factored into the WEAP model. However, recent literature suggests that salmonids in southerly locations, including Chinook salmon, may have thermal physiologies capable of tolerating higher water temperatures compared with more northerly populations that were evaluated to establish temperature tolerances (Zillig et al. 2021) so the WEAP model may overestimate temperature impacts on Chinook upstream migration. While some adult Chinook salmon may migrate at water temperatures greater than 65 °F (18.3 °C), a water temperature binary criterion of 65 °F (18.3 °C) was selected for adult Chinook salmon upstream passage with water temperature considered suitable when it was less than or equal to 65 °F (18.3 °C) and unsuitable when it was greater than 65 °F (18.3 °C) since the upper tolerable water temperature for adult Chinook salmon holding would be limiting for adult upstream passage (Valley Water 2023a ~~2019b~~).

Adult Chinook salmon select spawning sites with suitable substrate conditions and sufficient water depth and velocity to maintain circulation through the gravel, providing a clean, well-oxygenated environment for incubating eggs. The preferred flow velocity for spawning is generally in the range of 1 to 3 ft/s (Raleigh et al. 1984). Specifically, spawning Chinook salmon require clean, loose gravel in swift, relatively shallow areas. Because of their larger size, Chinook salmon can spawn in higher water velocities and use coarser substrates than other salmon species (Pacific Fishery Management Council [PFMC] 2014 ~~1999~~). Spawning Chinook salmon in California’s Trinity River reportedly preferred gravel and cobble from 2 to 6 inches in diameter that was less than 40 percent embedded in fine sediment (USFWS 1997). In Clear Creek (a tributary to the Sacramento River), spawning Chinook salmon used substrate sized between about 1 and 6 inches, with a preference for substrate between 1 and 3 inches (Giovanetti and Brown 2013). Raleigh et al. (1984) assumed that particles must be at least 0.5 inch in diameter to permit adequate percolation for successful embryonic development. In addition to substrate size, the percentage of fine sediment (in terms of cobble embeddedness) is also a primary determinant of spawning and incubation habitat quality, with survival of Chinook salmon embryos generally declining as the percentage of fine sediment in the redd increases above 25 percent (Bjornn and Reiser 1991). Continuous adult Chinook salmon spawning depth and velocity suitability curves were developed based on the principles presented in Bovee et al. (1998) and available literature on Chinook salmon spawning preferences to quantify the suitability of water depth and velocity conditions for Chinook salmon spawning (Valley Water 2023a ~~2019b~~). Suitability curves were generally irregularly shaped parabolas due to the variations in depth and velocity suitability reported in literature. Water depths greater than 0.23 feet and less than 3.30 feet were considered suitable for Chinook salmon spawning, with an optimal water depth of 1.13 feet. Water velocities greater than 0.30 ft/s and less than 5.50 ft/s were considered suitable for Chinook salmon spawning, with an optimal water velocity of 1.62 ft/s. Please refer to (Valley Water 2023a ~~2019b~~) for the specific suitability curves.

Following spawning, water depth and water temperature must be maintained within a suitable range during incubation for eggs to reach fry-emergence. Water depth is generally considered sufficient for Chinook salmon embryo incubation provided eggs are kept moist during incubation and redds are submerged when fry begin to hatch and emerge, with SWRCB (2007) assuming that the minimum depth for embryo incubation is approximately 0.1 feet above the bed surface. A water depth binary criterion of 0.1 feet was selected for Chinook salmon embryo incubation, with water depths considered suitable when it was 0.1 feet or greater and unsuitable when it was less than 0.1 feet. If the 0.1-feet water depth criterion was not met for one day of the forecasted incubation period, embryo incubation during that period was not considered successful (Valley Water 2023a ~~2019b~~).

Water temperature-related Chinook salmon embryo survival has generally been suggested to be optimal at approximately 43–54 °F (6–12 °C) (Myrick and Cech 2004). Based on a review of various water temperature studies on anadromous salmonid embryos summarized in McCullough et al. (2001), USEPA (2003) found that survival is optimized at constant water temperatures of about 39.2–53.6 °F (4–12 °C). Chinook salmon-specific studies indicate that Chinook salmon egg and alevin [3] survival decreased rapidly when water temperatures exceed approximately 56 °F (~13.3 °C) (Seymour 1956, Boles et al. 1988, USFWS 1999). Constant egg incubation temperatures between 42.5 °F and 57.5 °F were reported to result in normal development (Combs and Burrows 1957). Bratovich et al. (2012) identified an upper optimal water temperature index value of 56 °F (~13.3 °C) and an upper tolerable index value of 58 °F (14.4 °C) for Chinook salmon embryo incubation based on a review of water temperature studies, including some of those cited above, Myrick and Cech (2001), and NMFS (1993, ~~1997b,~~ 2002, 2014). As such, an upper optimal water temperature binary criterion of 56 °F (~13.3 °C) was selected for the Chinook salmon spawning and incubation based on an overall assessment of the various water temperature ranges reported to characterize the highest water temperature that could support high embryo survival in the literature and data review, with water temperature considered suitable when it was less than or equal to 56°F (~13.3°C) and unsuitable when it was greater than 56 °F (~13.3 °C). An upper tolerable water temperature binary criterion of 58 °F (14.4 °C) also was selected for the Chinook salmon spawning and incubation to represent the highest water temperature before embryonic mortality increases sharply based on a synthesis of the water temperature ranges in the reviewed literature and data, with water temperature considered suitable when it was less than or equal to 58°F (14.4°C) and unsuitable when it was greater than 58 °F (14.4 °C) (Valley Water 2023a ~~2019b~~).

Following emergence from redds, juvenile Chinook salmon are known to prefer slower water habitats than many other salmonid species (Quinn 2005) and have been reported to actively seek out slow backwaters, pools, or floodplain habitat for rearing (Sommer et al. 2001, Jeffres et al. 2008). However, juvenile Chinook salmon have been reported to show a clear preference for faster water (up to an average of about 1.8 ft/s) as they grow, consistent with trends found with

[3] Alevins are newly hatched salmon or trout that have broken free from the soft shell of the egg but still carry the yolk sac which provides nutrients. Alevins usually remain in the spawning gravels of the “redd” until they have absorbed the yolk sac and developed into fry.

salmonids in other rivers (Bjornn and Reiser 1991). Separate depth and velocity habitat suitability curves were identified through the FAHCE process and applied for fry and juveniles according to the same method applied for Chinook salmon spawning, but including data from Hampton (1997), Beakes et al. (2012 ~~2014~~), and Aceituno (1990) (Valley Water 2023a ~~2019b~~). Water depths greater than 0.00 feet and less than 5.72 feet are considered suitable for Chinook salmon fry rearing, with the habitat suitability curve forming a skewed bell shape that increases from 0 (e.g., not suitable) at 0.00 feet to 1 (e.g., most suitable) at the optimal water depth of 1.30 feet and decreases from 1 at 1.30 feet to 0 at the 5.72 feet. Water velocities from 0.00 ft/s to less than 2.55 ft/s are considered suitable for Chinook salmon fry rearing, with the habitat suitability curve forming a skewed bell shape that increases from 0 at 0.00 ft/s to 1 at the optimal water velocity of 0.28 ft/s and decreases from 1 at 0.28 ft/s to 0 at 2.55 ft/s. Water depths greater than 0.08 feet and less than 3.90 feet are considered suitable for Chinook salmon juvenile rearing, with the habitat suitability curve forming a skewed bell shape that increases from 0 at 0.08 feet to 1 at the an optimal water depth of 1.27 feet and decreases from 1 at 1.27 feet to 0 at the 3.90 feet. Water velocities greater than 0.00 ft/s and less than 3.27 ft/s are considered suitable for Chinook salmon juvenile rearing, with habitat suitability curve forming a skewed bell shape that increases from 0 at 0.00 ft/s to 1 at the optimal water velocity of 0.67 ft/s and decreases from 1 at 0.67 ft/s to 0 at 3.27 ft/s. Refer to (Valley Water 2023a ~~2019b~~) for figures and tables of the specific habitat suitability curves and further discussion can be found in Appendix F.

In-stream cover also is an important habitat component for juvenile Chinook salmon. Water depth (deep, low-velocity pools, and bank eddies), surface turbulence, instream structures, and substrate are all used as cover by juvenile Chinook salmon, with substrate being a primary source of escape and winter cover (Raleigh et al. 1986).

Water temperature is generally considered to be a key limiting factor for the Central Valley fall-run Chinook salmon juvenile rearing life stage, particularly during late spring. The preferred and tolerable water temperatures reported for juvenile Chinook salmon can be highly variable in literature due to differences in acclimation temperatures, local adaptation, food availability, and other site-specific conditions. The water temperature reported to allow for maximum growth of juvenile Central Valley fall-run Chinook salmon with maximal rations is 66.2 °F (19 °C) (Cech and Myrick 1999). Similar to results reported by Cech and Myrick (1999), Marine (1992) found that maximum growth rates of Sacramento River fall-run Chinook salmon were observed in juveniles reared at 62.6–68.0 °F (17–20 °C), with lower growth rates for juveniles reared at 69.8–75.2 °F (21–24 °C). USEPA (2003) determined the optimal growth for juvenile salmonids in general occurred when constant water temperatures ranged from 55.4–68 °F (13–20 °C) for unlimited food conditions or when constant water temperatures ranged from 50–60.8 °F (10–16 °C) for limited food conditions. Brett et al. (1982) determined that water temperatures of 66–68.9 °F (18.9–20.5 °C) were optimal for juvenile Chinook salmon from the Big Qualicum and Nechako Rivers fed to satiation, but the optimal growth water temperature decreased to 59 °F (15 °C) when juvenile Chinook salmon were fed at 60 percent of satiation. Overall, based on water temperature effects on growth, saltwater adaptation, and predation avoidance, Marine and Cech (2004) found that juvenile Central Valley fall-run Chinook salmon reared at water temperatures of 68 °F (20 °C) or greater experienced decreased growth, altered smolt physiology, and increased predation vulnerability compared with juveniles reared at water temperatures considered to be near optimal (55.4–60.8 °F). NMFS (2016) stated that optimal water temperatures for both Chinook salmon fry and juveniles range from approximately 54–61 °F (12–16 °C) based on Marine and Cech (2004) and Boles et al. (1988).

A literature review of water temperature effects on fry and juvenile Chinook salmon, including many of the citations discussed above and other studies evaluating suitable water temperatures for fry and juvenile Chinook salmon, was conducted to develop a continuous fry and juvenile rearing water temperature suitability curve (Valley Water 2023a ~~2019b~~). A fry and juvenile rearing water temperature suitability curve was constructed by overlaying two sets of binary water temperature criteria pertaining to “optimal growth” and “survival” based on the principles of a generic water temperature suitability curve presented in Bovee et al. (1998). A synthesis of the water temperature ranges in the reviewed literature identified an “optimal growth” water temperature range for fry and juvenile Chinook salmon as 50–61 °F (10–16 °C), with the lower limit based on USEPA (2003) and the upper limit based on (1) results of the laboratory study conducted by Marine and Cech (2004); (2) the upper optimal water temperature identified by Bratovich et al. (2012) for juvenile Chinook salmon rearing in the Central Valley; and (3) NMFS (2016). A synthesis of the water temperature ranges in the reviewed literature identified a “survival” water temperature range as 33–75 °F (0.6–24 °C), with the lower limit based on the thermal minima identified for juvenile Chinook salmon across studies presented by Myrick and Cech (2001) and the upper limit based on the lower end of the upper incipient lethal temperature range reviewed by Myrick and Cech (2001) for Chinook salmon. The water temperature ranges identified above synthesized the fry and juvenile Chinook salmon water temperature tolerances from multiple literature and data sources to best characterize the range of thermal tolerances of Chinook salmon in Coyote Creek, but individual studies may identify slightly different “optimal,” “optimal growth,” “tolerable,” or “survival” water temperature ranges depending on the Chinook salmon population studied (e.g., coastal or Central Valley), method of assessment (e.g., observation in field versus lab experiments), or the statistical time period considered (e.g., daily average versus weekly average). A continuous suitability curve was developed from these temperature criteria by fitting a third order polynomial function to the lower survivable temperature value (33 °F [0.6 °C]), lower optimal growth temperature value (50 °F [10 °C]), upper optimal growth temperature value (61 °F [16 °C]), and the upper survivable temperature value (75 °F [24 °C]) to create a biologically realistic variation in the water temperature suitability. The Fisheries Habitat Availability Estimation Methodology TM (Valley Water 2023a ~~2019b~~) provides further details, including a graph of the water temperature suitability curve. The water temperature suitability curve for fry and juvenile Chinook salmon rearing was used in the WEAP model (SEI and Valley Water 2020) to estimate how water temperature variations altered fry or juvenile rearing habitat availability, so the EIR references these criteria when discussing the effects of water temperature on fry or juvenile Chinook salmon rearing to be consistent.

In general, fall-run Chinook salmon in the Central Valley outmigrate from rivers as fry (Kimmerer and Brown 2006, Myers et al. 1997 ~~1998~~) since juveniles reared at water temperatures of 68 °F (20 °C) or greater experienced decrease growth, altered smolt physiology, and increased predation vulnerability compared with juveniles reared at water temperatures considered to be near optimal (Marine and Cech 2004). In order for Chinook salmon to migrate downstream, flow must be sufficient to provide a minimum water depth for juvenile Chinook salmon downstream migration and water temperatures must be suitable to support smoltification. A thalweg water depth criterion of 0.3 feet or greater was selected as the minimum water depth for assessing juvenile Chinook salmon downstream passage opportunities based on a review of available literature (CDFW 2013). Water temperatures that support smoltification for fall-run Chinook salmon range from 50–68 °F (10–20 °C), with approximately 50–63 °F (10–17.2 °C) being more optimal and water temperatures above approximately 63 °F (17.2 °C) reducing successful smoltification (Zedonis and Newcomb 1997). Bratovich et al. (2012) reviewed Chinook salmon literature on smoltification and downstream migration thermal tolerances (Kjelson and Brandes 1989; Marine 1997; Marine and Cech 2004; Zedonis and Newcomb 1997) and selected 63 °F (17.2 °C) and 68 °F (20 °C) as the Chinook salmon yearling and smolt outmigration upper optimal and upper tolerable water temperatures, respectively. As such, an upper tolerable water temperature binary criterion of 63 °F (17.2 °C) was selected to evaluate juvenile Chinook salmon downstream migration opportunities based on an overall assessment of the various water temperature ranges reported, with water temperature considered suitable for juvenile Chinook salmon downstream migration when it was less than or equal to 63 °F (17.2 °C) and unsuitable when it was greater than 63 °F (17.2 °C) (Valley Water 2023a ~~2019b~~).

Additionally, adequate concentrations of DO in fresh water are critical for the survival of all life stages of Chinook salmon (Carter 2008). Low DO concentrations can impact the swimming performance of migrating Chinook salmon and Chinook salmon avoided migrating when DO concentrations were below 5 mg/L (Carter 2008). At favorable incubation temperatures, growth of the embryos declined rapidly when DO was lower than 7 mg/L and alevin preferred oxygen concentrations between 8 and 10 mg/L (Carter 2008). Salmonid mortality can occur when oxygen concentrations fall below 3 mg/L for longer than 3.5 days (WDOE 2002).

Chinook Occurrence in the Fisheries Resources Study Area

Central Valley fall-run Chinook salmon have been observed in Coyote Creek since the mid-1980s. Their occurrence in the 1980s coincides with the initiation of the Central Valley hatchery and releases in San Francisco Bay and genetic evidence suggests they are of hatchery origin (Garcia-Rossi and Hedgecock 2002). Because the hatchery fish are released to San Francisco Bay and the Pacific Ocean as juveniles, they lack a strong homing instinct, which leads them to be more likely to stray to various river systems in the bay area like Coyote Creek and the Guadalupe River watersheds. Successful reproduction has been documented in the Coyote Creek Watershed (SCBWMI 2001). The majority of Chinook salmon spawning appears to be in the lowermost reaches of Coyote Creek (Smith 1998) but following the installation of a Vaki Riverwatcher at the Coyote Percolation Dam in 2019, adults have been observed migrating upstream through Metcalf Pond during both Pre-FERC Order and existing conditions. Few adult Chinook salmon have been observed upstream of Ogier Ponds (Valley Water, unpubl. data) but, Valley Water does not monitor for Chinook salmon spawning or rearing distribution; however, the presence of Chinook salmon redds would be recorded during steelhead spawning surveys if observed. No Chinook salmon redds have been observed in Coyote Creek during the limited number of steelhead spawning surveys to date (Valley Water 2021g, 2022b).

Chinook salmon travel through South San Francisco Bay, Alviso Slough, and the tidally influenced reaches of Coyote Creek when migrating into and out of Coyote Creek. Adult Chinook salmon were detected in Coyote Creek at the monitoring location near Metcalf Ponds in 2018 and 2019 (Pre-FERC Order Conditions) and 2020 (existing conditions) (Valley Water 2020e ~~2020d~~, 2021b). It is assumed that some rearing during smoltification may occur in San Francisco Bay, Alviso Slough, and the tidally influenced reaches of Coyote Creek, but spawning and rearing locations of Chinook salmon have not been clearly documented in the Study Area (Valley Water 2021h ~~2021i~~, Smith 2020). Spawning and rearing is likely to occur in suitable habitat outside of the tidally influenced reaches all the way to Anderson Dam. Run-timing and genetic analysis indicates that Chinook salmon occurring in the Coyote Creek watershed belong to the Central Valley fall-run ESU (Leidy 2007, Garcia-Rossi and Hedgecock 2002).

Chinook salmon have not been documented in Upper Penitencia Creek.

Pacific Lamprey

Pacific lamprey occur in the study area and are a California species of special concern with a status rating of "Moderate Concern" (Moyle et al. 2015). This rating denotes the species was "considered to be under no immediate threat of extinction" but were in "long-term decline of had naturally small, isolated populations which warrant frequent status re-assessment" (Moyle et al. 2015).

Pacific Lamprey Life History

Pacific lamprey are anadromous fish with three developmental stages: larvae, juvenile, and adult. Larvae reside entirely in freshwater before transforming into juveniles, which migrate to the ocean where they feed parasitically and grow into adults. These adults return to freshwater where they spawn and die.

Adult Pacific lamprey migrate into freshwater at a length of approximately 20 to 30 inches (Chase 2001). Once adults enter freshwater, they stop feeding and primarily expend energy towards upstream migration and sexual maturation (Johnson et al. 2015).

Freshwater entry typically occurs during winter and spring between January and June (Kan 1975, Chase 2001, Stillwater Sciences and Wiyot Tribe Natural Resources Department 2016, Parker 2018). The adult freshwater residence period can be divided into three distinct stages: (1) initial migration from the ocean to holding areas, (2) pre-spawning holding, and (3) secondary migration to spawning sites (Clemens et al. 2010, Starcevich et al. 2014). The pre-spawning holding stage begins when individuals cease upstream movement, generally in June or July, and continues until fish begin their secondary migration to spawn the following spring, generally in March or April (Robinson and Bayer 2005, Starcevich et al. 2014). Pacific lamprey do not necessarily home to natal spawning streams (Moyle et al. 2009, Spice et al. 2012). Instead, migrating adults appear to select spawning streams, at least in part, based on bile acid compounds secreted by larvae that act as migratory pheromones (Robinson et al. 2009, Yun et al. 2011). This mode of selecting spawning streams induces migratory adults to select locations where larval rearing has been successful as a result of suitable habitat and, therefore, has been called the "suitable river strategy" (Waldman et al. 2008).

Spawning typically takes place between March and June, and redds are constructed in gravel and cobble substrates within pool and run (sections without flow obstructions, even stream beds, and water flows faster than pools) tailouts or low-gradient riffles (Brumo et al. 2009, Gunckel et al. 2009). Larvae emerge from spawning gravels about 1 to 2 months after spawning, depending on water temperature, at a size of about 0.3 inches (Meeuwig et al. 2005; Brumo 2006). After hatching, the larvae drift downstream to backwater areas and burrow into fine sediment substrate, feeding on algae and detritus (Torgerson and Close 2004). Depending on growth rate, the larval phase lasts approximately 4 to 8 years, during which time individuals grow to about 6 inches (Dawson et al. 2015). After reaching sufficient size, larval Pacific lamprey transform into juveniles in late summer to fall (Dawson et al. 2015). During this metamorphosis, they develop eyes, a suctoral disc, sharp teeth, more-defined fins, and counter-shaded coloration (with silvery sides) in preparation for migration to the ocean (McGree et al. 2008, Manzon et al. 2015).

While little is known about Pacific lamprey juvenile outmigration timing in the study area, outmigration in other watersheds typically occurs at night in the winter and spring and is associated with high-flow events (Goodman et al. 2015). In the study area, summer and fall flows in the downstream portions of the two watersheds tend to be relatively low with intermittent, dry reaches; therefore, downstream migration likely occurs primarily in the winter and spring when sufficient stream flow is present to facilitate movement (before May).

After juveniles migrate to the ocean, they spend one to three years in the marine environment, during which time they parasitize a wide variety of ocean fish, including Pacific salmon, flatfish, rockfish, and pollock (Murauskas et al. 2013).

Pacific Lamprey Habitat Requirements

Pacific lamprey spawn in a wide range of river systems, from short coastal streams to inland tributaries of large rivers (USFWS 2019). The natural distribution of Pacific lamprey in California includes most streams with anadromous access and suitable spawning and rearing habitats (Swift and Howard 2009; Goodman and Reid 2012, 2017; Reid and Goodman 2016a). In general, over-summering habitat consists of protected areas associated with large cobble or boulder substrates, bedrock crevices, man-made structures such as bridge abutments, and large wood (Robinson and Bayer 2005, Lampman 2011, Starcevich et al. 2014). Effective spawning habitat consists of gravel and cobble substrates within pool and run tailouts and low-gradient riffles (Stone 2006, Brumo et al. 2009, Gunckel et al. 2009). Pacific lamprey can utilize a wide range of substrate sizes for redd construction, but most spawning occurs in locations with dominant particle sizes ranging from approximately 0.4 to 3.9 inches (10 to 100 mm) (Stone 2006, Gunckel et al. 2009). The principal habitat characteristics required for larvae are perennial water, fine sediments (sands and silts), and suitable water temperatures (Torgersen and Close 2004, Stone and Barndt 2005).

Unlike salmonids that can swim through or jump over high-velocity barriers, Pacific lamprey are specialized anguilliform [4] swimmers, with high-efficiency but relatively low-speed swimming (Mesa et al. 2003, Reid and Goodman 2016b). Swimming Pacific lamprey are often challenged by structural features (e.g., waterfalls, dams, fish ladders) (Goodman and Reid 2017). Often, they travel along the shallow periphery or even out of the water over wetted surfaces of a feature. This allows them to climb substantial waterfalls beyond the leaping or swimming ability of salmonids; however, simple angular edges or porous surfaces (e.g., grates) can block their passage.

The USFWS (2019) provides are review of Pacific lamprey habitat needs to date with regard to temperature ranges, tolerances, and preferences across life history stages. Pacific lamprey tolerate a range of temperatures from 41 to 77 °F (5 to 25 °C). Adult upstream migration and pre-spawning holding have been observed when daily average water temperatures are at or below 68 °F (20 °C) (Robinson and Bayer 2005, McCovey 2011, Starcevich and Clemens 2013). Although the upper and lower water temperatures at which spawning occurs are not well-defined, spawning has been observed at temperatures of 50–68 °F (10–20 °C) (Brumo 2006, Stone 2006). However, peak spawning occurs around 55-59 °F (13–15 °C) (USFWS 2019). Optimal embryo development occurs at water temperatures between 50 and 64 °F (10 and 18 °C). Meeuwig et al. (2005) found a sharp decline in embryo survival and increase in

[4] Elongate fishes with pelvic fins and girdle absent or reduced.

developmental abnormalities as incubation temperature increased from 64 to 71 °F (18 to 22 °C). Survival of larvae is optimal over a range of 50–64 °F (10–18 °C) with a sharp decline at 71 °F (22 °C). Water temperature suitability for juvenile downstream migration has not been documented. Although specific tolerances to DO are unknown, the species is known to be tolerant of low oxygen concentrations (Brumo 2006, Beamish 1980).

Pacific Lamprey Occurrence in the Fisheries Resources Study Area

Pacific lamprey have been documented in streams in the northern portion of Santa Clara County and are present in mainstem Coyote Creek and Upper Penitencia Creek (NMFS 2011; City of San José 2012; Valley Water 2020a, 2021a). Pacific lamprey larvae were reported in Coyote Creek by Leidy (2007). In Coyote Creek, Pacific lamprey larvae reportedly are common downstream of the percolation pond discharge (Smith 2013).

Recent observations of Pacific lamprey migrating upstream and downstream have occurred at the Coyote Percolation Facility Fish Ladder in 2019, 2020, and 2023 (Valley Water 2020a, 2021a, 2024 ~~2023d~~). Four adult Pacific lamprey were observed in Upper Penitencia Creek, in proximity to Highway 680, during a spawning survey in 2011 (NMFS 2011). Over the last three years, a few outmigrating juveniles have been observed in the tidally influenced part of the study area where Coyote Creek discharges into the South San Francisco Bay (Otolith Geochemistry & Fish Ecology Laboratory 2021, 2023) even though the sampling methods are not optimized to capture Pacific lamprey. The documented lamprey juveniles likely reared in Coyote Creek for 5-7 years before being observed in the University of California, Davis Trawl surveys, assuming they migrated from the closest river system to where they were observed. With the completed installation of the fish passage facility at Coyote Percolation Dam, it is reasonable to assume, depending on hydrologic conditions, that Pacific lamprey could migrate up Coyote Creek to the base of Anderson Dam.

Because monitoring for Pacific lamprey is opportunistic and few observations have occurred in Coyote Creek Watershed, there is no known changes in occurrence observed between Pre-FERC Order and existing conditions that can be deciphered from the data available.

Monitoring for lamprey in Coyote Creek upstream of the tidally influenced areas is opportunistic so their current occurrence in the watershed is unknown but lamprey adults were observed on the Vaki Riverwatcher at Coyote Percolation Facility in 2023 so they are present under existing conditions throughout Coyote Creek and likely in Upper Penitencia Creek (Valley Water 2024 ~~2023d~~).

Sacramento Hitch

Sacramento hitch occur in the study area and are a California species of special concern (CNDDB 2023 ~~CDFW 2018c~~).

Sacramento Hitch Life History

Sacramento hitch are omnivorous cyprinids that feed in streams on filamentous algae, as well as aquatic and terrestrial insects (Moyle 2002). They feed in open water, and juvenile Sacramento hitch (2–3 inches in length) will feed on drift at the heads of pools in the summer (Moyle 2002). Sacramento hitch primarily feed, and are most active, during the day (Moyle 2002).

Sacramento hitch can spawn as early as February and as late as July. Spawning is known to occur in riffles of streams after increased flows resulting from spring rains (Moyle 2002). Sacramento hitch require clean, fine to medium gravel for spawning, and water temperatures of 57–79 °F (14–26 °C) (Moyle 2002). Sacramento hitch prefer to spawn in shallow water; however, the species can also spawn in ponds and reservoirs. Sacramento hitch are known to hybridize with Sacramento blackfish and southern coastal roach (Moyle 2002).

Female Sacramento hitch have been known to contain more than 26,000 eggs, but larger numbers are likely possible in the correct conditions (Moyle 2002). Males fertilize the eggs immediately after release, and the fertilized eggs then sink into the gravel below (Moyle 2002). The eggs absorb water and swell considerably, about four times their original size, which lodges them into the gravel (Moyle 2002). Hatching occurs 3 to 7 days later at temperatures of 59–72 °F, with larvae free-swimming in 3 to 4 days (Moyle 2002). Young Sacramento hitch spend about 2 months in shallow water or near aquatic plant beds before moving to open water when they are around 2 inches in length (Moyle 2002). Juvenile rearing can occur year-round.

Sacramento Hitch Habitat Requirements

Sacramento hitch prefer warm, lowland waters, but are also known to be abundant in cool, clear streams (Moyle 2002). They can reside in clear streams, turbid sloughs, lakes, and reservoirs (Moyle et al. 2015). In streams, smaller fish are often associated with beds of aquatic or emergent vegetation that are utilized as cover, and larger fish reside in deep pools with overhanging trees (Moyle 2002). Sacramento hitch spawn primarily in riffles with clean, fine to medium sized gravels in low-gradient streams, although spawning may also occur in ponds or reservoirs (Moyle 2002). Juvenile (2–3 inches) Sacramento hitch have also been seen schooling at pool edges and adults have been observed in undercut banks bordering pools (Leidy 2007). Sacramento hitch are known to prefer stream habitat that includes riffles and shallow waters with smaller gravel (Moyle et al. 2015). Sacramento hitch are also associated with unshaded pools with low water clarity and silt or sand substrates, where they can occur in high densities (Leidy 2007). They are known to use flooded marshes as cover for their young (Moyle 2002). Like non-native fishes in the San Francisco estuary region, Sacramento hitch tend to utilize middle to lower reaches of large streams (Leidy 2007).

Sacramento hitch have the highest temperature tolerance of any native fish in the Central Valley, with juvenile fish able to acclimate to temperatures around 86 °F (29 °C) in the lab (Moyle 2002). However, adults tend to select temperatures of 80–84 °F (27–29 °C) and are most abundant in water temperatures cooler than 77 °F (25 °C) during the summer (Moyle 2002). Sacramento hitch can also survive in brackish water, with reports of Sacramento hitch being found in salinities as high as 9 parts per thousand (ppt) (Moyle 2002). There is little known about DO tolerances. However, because the species is tolerant of elevated temperatures, it is likely the species is tolerant of commonly associated low DO levels relative to other native fish (i.e., below 7 mg/L).

Sacramento Hitch Occurrence in the Fisheries Resources Study Area

In Coyote Creek, downstream of the Anderson Dam, Sacramento hitch have been documented in several surveys (Buchan and Randall 2003; Leidy 2007; Moore et al. 2008; Leicester and Smith 2014, Leicester and Smith 2015; Valley Water 2020a, 2021a, 2021g ~~2021d~~, 2022). Although there has not been comprehensive density sampling along the entire length of Coyote Creek for hitch, they seem to be in higher abundance or occur more often closer to the dam (Leicester and Smith 2014, Leicester and Smith 2015). Leidy (2007) observed large adult Sacramento hitch (less than 280 mm fork length) in Coyote Creek near undercut banks along pools, while schools of smaller Sacramento hitch (less than 125 mm fork length) were found along edges of pool habitats (Leidy 2007).

In Coyote and Anderson Reservoirs, California Department of Fish and Game (CDFG; now CDFW) reportedly collected Sacramento hitch during surveys conducted in the 1970s and 1980s (Leidy 2007). Valley Water did not document hitch in Anderson Reservoir during boat-based electrofishing and hook and line surveys in 2017 and 2019 (Valley Water 2020b) or in limited exploratory boat-based electrofishing surveys in 2023 (Valley Water 2023c ~~C. Leal Pers. comm. 2023~~). Also, while Valley Water did capture Sacramento hitch during the FOCP drawdown through fyke net trapping downstream of the reservoir (Valley Water 2021d ~~2021c~~), the fyke net was located over 30 meters downstream of the dam so it was not possible to differentiate if the Sacramento hitch came from the reservoir or were already using wetted areas between the fyke trap and the dam (Valley Water 2021d ~~2021c~~). However, Valley Water did document Sacramento hitch in Coyote Reservoir using boat-based electrofishing in 2019 (Valley Water 2020c); therefore, while abundance in Anderson Reservoir under existing conditions baseline is likely very low compared to total abundance throughout the watershed, there is still a possibility that Sacramento hitch can occur in Anderson Reservoir if they move from Coyote Reservoir down to Anderson Reservoir. It is also unknown if Sacramento hitch occur in the northern arm tributaries of Anderson Reservoir, but if they do, these tributaries could also seed Anderson Reservoir with this species.

Sacramento hitch have not been observed in Upper Penitencia Creek pre-FOCP or during current conditions.

Although monitoring for Sacramento hitch is opportunistic, there have been no major changes in occurrence observed between Pre- and Post-FERC Order conditions that can be deciphered from the data available. Sacramento hitch are abundant, less sensitive to water temperature than other native fish, and can spawn in a variety of habitat so they will likely occur anywhere that provides enough water depth and some kind of spawning habitat.

Although there have been no observations of Sacramento hitch within the tidally influenced portions of Coyote Creek Watershed, given the salinity tolerances outlined above, and the opportunistic monitoring that is conducted for this species as well as within the tidal reaches, it is possible Sacramento hitch could occur within the tidally influenced portions of Coyote Creek.

Southern Coastal Roach

Southern coastal roach occur in the study area and are a California Species of Special Concern (CDFW 2023).

Southern Coastal Roach Life History

Spawning is temperature dependent and typically occurs between March and July when water temperature exceeds 60 °F (Moyle et al. 2015). Southern coastal roach form large aggregations for spawning within habitats that are shallow in depth, contain flow, and contain coarse substrates 3–5 cm in diameter (Moyle 2002, Moyle et al. 2015). Females deposit eggs into crevices between rocks and males fertilize the eggs (Moyle et al. 2015). Eggs hatch within 2–3 days and larvae remain in the gravel until swimming abilities are developed (Moyle et al. 2015). The species usually becomes mature at 2, and sometimes 3, years of age (Moyle 2002).

Southern Coastal Roach Habitat Requirements

Southern coastal roach occur in a wide array of habitats and are tolerant of intermittent surface water (Moyle et al. 2015). The species is tolerant of varied temperatures (warmwater temperatures up to 95 °F [30-35 °C]) and low levels of DO (1-2 mg/L) (Moyle et al. 2015) but are intolerant of saline environments (Moyle 2002). Southern coastal roach are common in reaches that support native fish but may be less present in reaches that contain piscivorous (fish-eating) fish, particularly non-native species (Moyle 2002). The species is most abundant in reaches where between 0 and 2 other species are present (Moyle 2002). In streams, the species can be found in open waters of large pools as well as riffles and other shallow habitats (Moyle 2002). The species is omnivorous and feeds on filamentous algae, aquatic insects, and small crustaceans (Moyle 2002).

Occurrence in the Fisheries Resources Study Area

Southern coastal roach are present in the study area and have been recently observed from Ogier Ponds to Anderson Dam (Valley Water 2008a, 2008b ~~2008~~, 2021a, 2022). It is reasonable to assume that, depending on hydrologic conditions, southern coastal roach could be present within Coyote Creek from the estuary to Anderson Dam. Southern coastal roach are also present within Upper Penitencia Creek (Valley Water 2021a, Smith 2021).

Although monitoring for roach is opportunistic, there have been no major changes in occurrence observed between pre- and current conditions. Southern coastal roach are less sensitive to water temperature than other native fish, and can spawn in a variety of habitat so they will likely occur anywhere that provides enough water depth and some kind of spawning habitat.

Southern coastal roach have not been documented in the tidally influenced portions of Coyote Creek, and given the habitat requirements outlined above, it is unlikely the species is present within this reach.

San Francisco Bay-Delta Longfin Smelt

The San Francisco Bay-Delta DPS of longfin smelt (longfin smelt) occurs in the tidally influenced portions of Coyote Creek as well as Alviso Slough, ~~and~~ is a federal candidate species for ESA protection, is listed as endangered under the ESA (89 FR 61029), and is listed as threatened under the California Endangered Species Act (USFWS 2021, CDFW 2018b).

Longfin Smelt Life History

Longfin smelt are a facultatively anadromous smelt species that can tolerate a wide range of salinities (Moyle 2002, CDFW 2010). Most longfin smelt live for up to two years, although some age three longfin smelt have been observed (CDFG 2007, CDFW 2010). Adult and juvenile longfin smelt generally occur in the open waters of San Francisco Bay and coastal marine habitats during the late spring and summer months (Moyle 2002, Barros et al. 2022a ~~2021~~). Adults migrate to low-salinity tidal habitats beginning in October to begin spawning (Moyle 2002). Spawning typically occurs from February to April at water temperatures of 44.6–58.1 °F (7 °C–14.5 °C) but can occur as early as November and as late as June (Moyle 2002, Otolith

Geochemistry & Fish Ecology Laboratory 2021). Embryos hatch in about 40 days at 44.6 °F (7 °C) (Moyle 2002). Newly hatched longfin smelt are buoyant and are naturally swept downstream into more brackish parts of the estuary (Moyle 2002). In the Bay-Delta, they are most abundant in San Pablo and Suisun bays (Moyle 2002).

Longfin Smelt Habitat Requirements

Longfin smelt inhabit nearshore waters to estuaries and lower portions of freshwater streams (Garwood 2017). Little scientific literature exists regarding the habitat of each life-history stage of longfin smelt. Larvae, juveniles and adults are typically found in salinity ranges less than 2 ppt (Rosenfield 2010). Although exact locations of spawning adults are unknown, within the San Francisco Bay spawning appears to occur near the fresh-salt water mixing zone (Rosenfield 2010). It is thought the selection of a spawning site may be within an area that allows the transport of larvae into the fresh-salt water mixing zone as it is both a productive and turbid area within the San Francisco Bay (Rosenfield 2010).

Longfin smelt are found in a wide variety of water temperatures and salinities (including freshwater to almost pure seawater) during their life cycle (Moyle 2002, CDFG 2007). Longfin smelt prefer salinities in the range of 15–30 ppt and appear to be limited by high water temperatures, as they rarely are found in water temperatures greater than 68.0 °F (20 °C) (Moyle 2002, CDFG 2007, The Bay Institute et al. 2007, Rosenfield 2010). Longfin smelt forage in tidally influenced portions of river channels where copepods and mysid shrimp are abundant (Barros et al. 2022a ~~2021~~, Lewis et al. 2020, Valley Water 2013). Spawning occurs at night within sandy or gravelly substrates, rocks, and aquatic vegetation (Moyle 2002). Longfin smelt spawn adhesive eggs which are likely deposited on rocks or aquatic plants upon fertilization; however, exact locations of spawning and egg deposition remain unknown (Gross et al. 2022). Successful recruitment of longfin smelt appears to be positively correlated with winter and spring freshwater outflow, as higher inputs of freshwater likely provide greater quantities of brackish water rearing habitat for longfin smelt larvae (Moyle 2002, Lewis et al. 2020).

Longfin smelt occur in turbid environments and seem to tolerate and even prefer high levels of suspended sediment. Following several atmospheric rivers in December 2022 and January 2023, Coyote Creek suspended sediment and turbidity levels were very high. While turbidity and suspended sediment levels remained high where Coyote Creek discharges into the sloughs, the University of California, Davis trawl effort by the Otolith Geochemistry & Fish Ecology Laboratory documented over 200 longfin smelt in that area that appeared to be preparing for spawning (Otolith Geochemistry & Fish Ecology Laboratory 2023).

Longfin Smelt Occurrence in the Fisheries Resources Study Area

Longfin smelt occur in the South San Francisco Bay, including tidally influenced reaches of Coyote Creek and Alviso Slough, seasonally from October through April as adults and from April through May as post-larval recruits (Lewis et al. 2020; Moyle 2002; Otolith Geochemistry & Fish Ecology Laboratory 2021, 2022). Fish sampling in Coyote and Alviso sloughs has detected the species October through May (Hobbs et al. 2012 as cited in Valley Water 2013; Otolith Geochemistry & Fish Ecology Laboratory 2021, 2022, 2023). Adult longfin smelt have been observed spawning or preparing to spawn in restored salt ponds and tidal sloughs within the study area (Lewis et al. 2020, Barros et al. 2022a ~~2021~~; Otolith Geochemistry & Fish Ecology Laboratory 2021, 2022, 2023). Post-larval recruits forage in restored salt ponds and tidal sloughs of the South San Francisco Bay before leaving the study area and migrating seaward into deeper, cooler bay and coastal marine habitats during the summer (June through September) (Barros et al. 2022b ~~2022~~; Moyle 2002). To date, longfin smelt have only been documented in intertidal areas and have not been documented further upstream in Coyote Creek and Upper Penitencia Creek. Given habitat criteria outlined above, it is unlikely for longfin smelt of any life-history stage to occur upstream of the tidally influenced portions of Coyote Creek Watershed.

Under the Pre-FERC Order Baseline and through existing conditions, “Persistent and occasionally dense” aggregations of Longfin smelt have been observed in the tidally influenced reaches of Coyote Creek and Alviso Slough between 2011 and 2022 (Lewis et al. 2020; Otolith Geochemistry & Fish Ecology Laboratory 2021, 2022, 2023). Longfin are not present near the Seismic Retrofit construction area or in freshwater areas of Coyote Creek. The first documented adults in spawning condition occurred in 2017.The number of observed individuals has increased each subsequent year starting in 2011 with the highest number of individuals observed in 2022 and 2023 during existing conditions (Lewis et al. 2020; Otolith Geochemistry & Fish Ecology Laboratory 2021, 2022, 2023). The first documented adults in spawning condition ~~t~~ occurred in 2017.

White Sturgeon

White sturgeon occur in South San Francisco Bay and are a California Species of Special Concern.

White Sturgeon Life History

White sturgeon juveniles and adults migrate between fresh and salt water at multiple stages of their life cycle other than the spawning period. Reports of maximum size and age of white sturgeon are as great as 6-meter fork length (FL; the distance from the tip of the snout to the end of the middle caudal fin rays) (820 kg) and greater than 100 years old, although they generally do not exceed 2-meter FL or 27 years of age. Maturation depends largely on temperature and photoperiod, with males maturing in 10–12 (75–105 cm FL) years and females in 12–16 years (95–135 cm FL) (Moyle 2002).

White sturgeon have high fecundities and females may spawn up to 200,000 eggs. White sturgeon spawn in large, mainstem rivers, with the majority of white sturgeon in San Francisco Bay spawning in the Sacramento River, followed by the Feather and San Joaquin Rivers (Moyle 2002). Eggs become adhesive after fertilization and adhere to the substrate until they hatch 4 to 12 days later, depending on temperature. Once the eggs have been deposited, the adults move back downstream to the estuary. Larvae hatch in 12 weeks, depending on temperature.

Little is known about white sturgeon in the South San Francisco Bay due to their long lifespan and the difficulty of tracking over time (Schreier et al. 2022, Walter et al. 2022). However, they are similar to other sturgeon species, and exhibit delayed maturation and irregular reproduction (Zeug et al. 2014). Juvenile and adult white sturgeon can be found year-round in the San Francisco Bay and primarily spawn in the Sacramento River in late winter and spring (Zeug et al. 2014).

White Sturgeon Habitat Requirements

Although white sturgeon migrate between freshwater and salt water, they primarily occur in brackish portions of estuaries where they tend to concentrate in deep sections having soft substrate and cool water temperatures (59–71 °F [15–22 °C]) (Grans et al. 2010, Moyle 2002, Patton et al. 2020). They move according to salinity changes and may swim into intertidal zones to feed at high tide (Patton et al. 2020). White sturgeon are benthic feeders, and adults may move into food-rich areas to forage. Juveniles consume mainly crustaceans, especially amphipods and opossum shrimp (Moyle 2002). Adult diets include invertebrates (mainly clams, crabs, and shrimp), as well as fish, especially herring, anchovy, striped bass, and smelt (Otolith Geochemistry & Fish Ecology Laboratory 2021).

Spawning occurs in large mainstem rivers over deep gravel riffles or in deep pools with swift currents and rock bottoms between late February and early June when temperatures are between 8–19 °C (Moyle 2002).

White Sturgeon Occurrence in the Fisheries Resources Study Area

White sturgeon use the tidally influenced reaches of the study area for rearing and foraging. White sturgeon populations are estimated to be high in the tidally influenced reaches of Coyote Creek, likely due to historical inaccessibility (i.e., shelter from fishing) and abundance of prey (Buckmaster and Hobbs 2009). White sturgeon readily migrate into South San Francisco Bay sloughs in the springtime to feed on prey that are seasonally abundant (Otolith Geochemistry & Fish Ecology Laboratory 2021, 2022). White sturgeon migrate out of these sloughs when water temperatures increase, as they prefer temperatures from 59–71 °F (15–22 °C) (Grans et al. 2010). Fish sampling in Coyote and Alviso sloughs has detected the species during the cooler months (November through May), with limited detections during warmer summer months (June through October) (Otolith Geochemistry & Fish Ecology Laboratory 2021, 2022). To date, white sturgeon have only been documented in intertidal areas and have not been documented further upstream in Coyote Creek or Upper Penitencia Creek.

Because observations of white sturgeon are opportunistic during the University of California, Davis trawl effort by the Otolith Geochemistry & Fish Ecology Laboratory, as well as citizen science initiatives (iNaturalist 2023) in South San Francisco Bay, including the tidally influenced portions of Coyote Creek Watershed, there are no known changes in occurrence or abundance observed between Pre-FERC Order Baseline Conditions and the existing conditions baseline that can be deciphered from the data available.

Green Sturgeon Southern Distinct Population Segment

The Green Sturgeon Southern DPS (green sturgeon) occurs in South San Francisco Bay and is protected as Threatened under the ESA (CDFW 2021). Critical habitat is designated under the ESA within the lowermost, tidally influenced reaches of Coyote Creek to approximately 120 feet upstream of the North McCarthy Boulevard Bridge crossing over Coyote Creek (50 CFR Part 226).

Green Sturgeon Life History

Little is known about green sturgeon in the South San Francisco Bay. The species is currently thought to have spawning fidelity in natal streams and is only known to spawn in the Feather River and the upper reaches of the Sacramento River between April and July, although early spring and later summer spawning may also occur (NMFS 2018). Juvenile and adult green sturgeon could be in South San Francisco Bay year-round and some adults through San Francisco Bay to the Sacramento River during their spawning migration (NMFS 2018). Juveniles appear to spend 1 to 4 years rearing in fresh and estuarine waters (Beamesderfer and Webb 2002, Moyle et al. 1995).

Green Sturgeon Habitat Requirements

Green sturgeon spawn in deep pools in large, turbulent, freshwater river mainstems (Moyle et al. 1992). Juvenile green sturgeon may be found in freshwater or brackish water environments but are generally between 1-2 years old before entering seawater, while adults can be found in freshwater, brackish water, or seawater environments (Allen and Cech Jr. 2006). Although adult green sturgeon are often found in brackish water habitats, the energetic costs of individuals located in environments with salinities ranging between freshwater and brackish water were virtually the same (Allen and Cech Jr. 2006).

Critical habitat was designated for the DPS of green sturgeon on October 9, 2009 (74 Federal Register 52300) and includes coastal marine waters within 60 fathoms depth from Monterey Bay, California to Cape Flattery, Washington, including the Strait of Juan de Fuca to its United States boundary. Designated critical habitat also includes the Sacramento River, lower Feather River, lower Yuba River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay. Critical habitat also includes San Francisco Bay encompassing all tidally influenced areas up to the mean high-water elevation in the bay and its tributaries (NMFS 2009); this designation includes the lowermost, tidally influenced reaches of Coyote Creek. The Primary Biological Features determined by NMFS to be essential for the conservation of the sDPS include deep holding pools (less than or equal to 16.4 feet for both upstream and downstream holding of adult or subadult fish), with adequate water quality and flow to maintain the physiological needs of the holding adult or subadult fish. Sediment quality (i.e., chemical characteristics) is necessary for normal behavior, growth, and viability of all life stages. This includes sediments free of elevated levels of contaminants (e.g., selenium, polyaromatic hydrocarbons, and pesticides) that may adversely affect green sturgeon.

Green Sturgeon Occurrence in the Fisheries Resources Study Area

Although green sturgeon have not been documented and are not generally expected to occur within the fisheries study area, critical habitat under the ESA is designated within the tidally influenced reaches of Coyote Creek. Green sturgeon presumably forage in the South San Francisco Bay; however, only one definitive record has been documented of a radio-tagged individual tracked to a telemetry receiver on the Dumbarton Railroad Bridge (Spenst et al. 2012 as cited in Valley Water 2013). Given no observations of green sturgeon have occurred during the monthly fish sampling in Coyote and Alviso sloughs (Otolith Geochemistry & Fish Ecology Laboratory 2023), it is unlikely for green sturgeon to occur within the tidally influenced portions of Coyote Creek, upstream of the tidally influenced portions of Coyote Creek, or Upper Penitencia Creek.

Riffle Sculpin

Riffle sculpin (*Cottus gulosus*) is listed by the State of California as a Species of Special Concern. Riffle sculpin are present in Upper Penitencia Creek but have not been observed in Coyote Creek. The population of riffle sculpin (*Cottus* sp.) in drainages flowing west or southwest along the Coast Range Mountains of California, including the Coyote Creek watershed, was determined to be genetically and geographically distinct from other populations in a recent, comprehensive review of the *Cottus gulosus* complex (Moyle and Campbell 2022). Moyle and Campbell (2022) now refer to sculpin in the Coyote Creek watershed as *Cottus ohlone* or coastal riffle sculpin. A subspecies was identified *C. o. ohlone* (Ohlone riffle sculpin), which includes *C. ohlone* in Coyote Creek watershed (Moyle and Campbell 2022), although the *C. ohlone* nomenclature has not been completely adapted yet by the scientific community at large and regulatory status of *Cottus ohlone* has not been formally reevaluated by the state of California at this time. Despite the inconsistencies of the species name at this time, "riffle sculpin" is generally used in this EIR.

Riffle Sculpin Life History

Riffle sculpin can grow up to 6 inches; however, most adults are typically 2–3 inches long (Moyle et al. 2015). Adults are thought to mature at the end of their second year, with spawning occurring from February through March (Moyle 2002). Spawning occurs under rocks in swift riffles or inside cavities in submerged logs (Moyle et al. 2015). Males choose spawning locations and remain in the nest to guard embryos until they hatch (Moyle et al. 2015). A female can lay between 400 and 1,000 eggs with embryos typically hatching within 11–24 days later at water temperatures ranging from 59–75 °F (15–24 °C) (Moyle 2002). Fry are benthic and do not move far after emerging from their nests. Juveniles and adults are poor dispersers and generally stay close to where their natal nests were located (Moyle et al. 2015).

Riffle sculpin are opportunistic feeders and feed mostly at night. They prey primarily on benthic macroinvertebrates, mainly the larvae of caddisflies, stoneflies, and mayflies, but also eat amphipods and small fish (Moyle 2002).

Riffle Sculpin Habitat Requirements

Riffle sculpin are found exclusively in permanent headwater streams with rocky or gravel substrates. They prefer cold, well-oxygenated streams with DO levels near saturation, which restricts their occurrences to areas with ample flowing water (Moyle et al. 2015). Riffle sculpin are most abundant in streams with water temperatures that do not exceed 77–79 °F (25–26 °C) while temperatures above 86 °F are typically lethal (Moyle 2002).

They occupy riffles and pools but prefer areas that have adequate cover in the form of rocks, gravel, woody debris, or undercut banks (Moyle et al. 2015). Riffle sculpin also require suitable habitat for benthic macroinvertebrates, their primary prey source (Moyle et al. 2015). Riffle sculpin are typically found in headwater streams and upper watersheds and generally utilize the same headwater and upper watershed habitats as steelhead and Pacific lamprey (Leidy 2007).

Riffle Sculpin Occurrence in the Fisheries Resources Study Area

Riffle sculpin are common throughout Upper Penitencia Creek (Valley Water 2021a). The species has not been observed in Coyote Creek (below Anderson Reservoir), Anderson Reservoir, and wouldn't be present in the intertidal portions of Coyote Creek Watershed.

Essential Fish Habitat

The study area includes areas designated as EFH for various life-history stages of coho and fall-run Chinook salmon in the Santa Clara Hydrologic Unit [2205], coastal pelagic species and Groundfish. Affected portions of coho and Chinook salmon EFH include migratory corridors, spawning habitat, and rearing habitat. Although there were potential historical reports of coho salmon in Coyote Creek Watershed, the habitat conditions likely did not support this species, and the credibility of the historic accounts is unknown. Coho salmon are not currently present but ~~were not historically present and are not currently present in the Coyote Creek Watershed,~~ coho salmon EFH is designated in Coyote Creek downstream of Anderson Dam (Leidy et al. 2005b, Leidy 2007). In this EIR, impacts on coho salmon EFH are indirectly addressed through evaluation of impacts on Chinook salmon and steelhead habitat. The tidal areas of Coyote Creek fall under Costal Pelagic and Groundfish EFH. These areas are defined as the waters and substrate necessary to fish for spawning, breeding feeding, or growth to maturity. The area of EFH for groundfish and pelagic fish affected by the Project is a very small proportion (<0.01%) of the total EFH designated for the species along the Pacific Coast. ~~These habitats are present in a very limited area of the study area and are not expected to be impacted by project actions.~~ Coastal pelagic and groundfish EFH would have similar impacts as those on the estuarine species' (i.e., Impacts FR-1f, FR-1g, and FR-1h) and are analyzed by applying the estuarine species impacts analysis to consideration of the impacts on pelagic and groundfish species and EFH. As described in Impacts FR-1f, FR-1g, and FR-1h, increased suspended sediment is not anticipated to substantially decrease the quality of estuarine species' habitat. In addition, groundfish and pelagic species are adapted to periodic pulses of high sediment and have the ability to swim away from areas of temporary poor habitat quality. Coastal pelagic and groundfish EFH would have similar impacts as those on the estuarine species' and can be considered indirectly analyzed through the impacts of these species.

3.4.1.2 Points of Interest in the Study Area

The FAHCE TWG identified POIs (**Figure 3.4-2**), selected to represent the most ecologically relevant results for salmonids, used as nodes (or important locations) in development of the FAHCE WEAP model whose output was used to help predict fisheries impacts. The locations are also useful to delineate geographic features used for discussion throughout the impact analysis.

The details of the POIs can be found in the *Methods for Establishing Reaches of Interest and Points of Interest* (FAHCE TWG 2016) and **Table 3.4-3** but some of the relevant geographic locations for this EIR are described here and shown in **Figure 3.4-2**. COYO1 is at Highway 237 which is near the most upstream extent of the tidally-influenced part of the study area, COYO 2 is downstream of the Coyote Creek confluence with Upper Penitencia Creek with Coyote Creek, while COYO 3 is downstream of the Coyote Creek confluence with Silver Creek. COYO6 is downstream of the Coyote Percolation Ponds. COYO7 is upstream of Golf Drive and downstream of Ogier Ponds which is near the extent of the CWMZ as defined in the FAHCE *Settlement Agreement.* COYO 8-10 are in the FCWMZ with COYO8 occurring directly upstream of Ogier Ponds, COYO9 near the Madrone gauge which is often used as an assessment point for measuring flows and water quality and COYO10 is closest to the dam. Finally, all of the UPEN POIs denote locations in Upper Penitencia Creek. Riffle sculpin are present and steelhead may be relocated, if needed, under the Fish Rescue and Relocation Plan (Stillwater Sciences 2020a; see Section 2.5.6.1.6.4) at UPEN4.

Figure 3.4-2. Points of Interest in Coyote Creek and Upper Penitencia Creek (sources: ESRI 2016 and Valley Water 2023a ~~2020a~~)

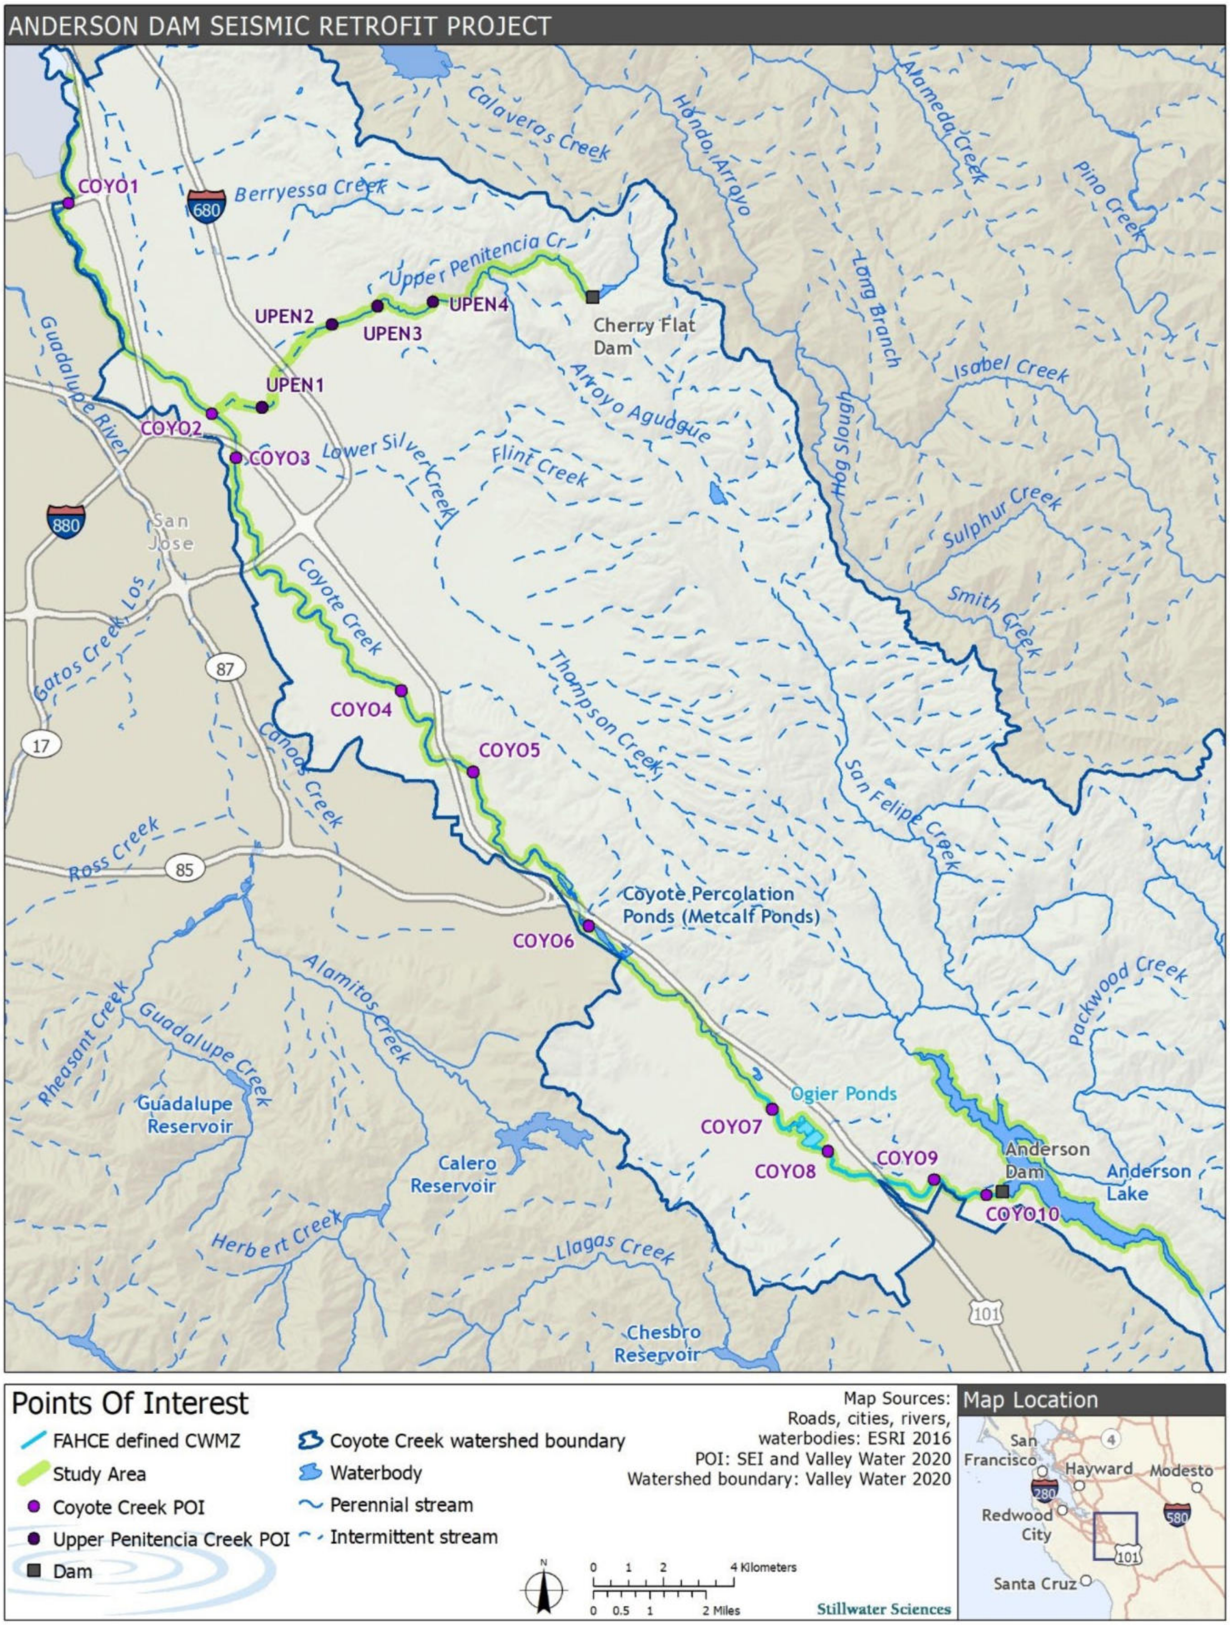

Table 3.4-3. Location of Points of Interest in Coyote Creek. Distances shown in feet upstream from San Francisco Bay

POI ID	Points of Interest	Distance to San Francisco Bay (feet)
COYO1	Highway 237	59,000
COYO2	Downstream of Penitencia Creek	87,800
COYO3	Downstream of Silver Creek	92,800
COYO4	Singleton Road	127,500
COYO5	Above Hellyer Avenue	141,500
COYO6	Downstream of Coyote Percolation Pond	167,500
COYO7	Above Golf Drive	192,000
COYO8	Above Ogier Ponds	204,000
COYO9	Below San Felipe Pipeline	214,400
COYO10	Below Anderson Reservoir	222,600
UPEN1	Upper Penitencia Creek below Mabury Diversion	94,000
UPEN2	Upper Penitencia Creek at Piedmont Road	105,000
UPEN3	Upper Penitencia Creek at Dorel Drive	110,000
UPEN4	Upper Penitencia Creek at Alum Rock YSI	121,500

3.4.1.3 Hydrology

Anderson Dam is an on-stream reservoir on Coyote Creek. The inflow into Anderson Reservoir can be split into two separate sub-watersheds:

1. Uncontrolled natural inflow from the northern arm reservoir tributaries (Packwood Creek and Las Animas Creek), excluding flows from Coyote Reservoir; and
2. Flows from Coyote Reservoir (controlled releases from the dam outlet and uncontrolled flow when the Coyote Reservoir is spilling).

In normal water years (50 percent exceedance probability), monthly uncontrolled natural inflow to Anderson Reservoir ranged from 8 AF in the late summer (September) to 2,489 AF in the winter (February). In wet water years (10 percent exceedance probability), monthly natural inflow ranges from 129 AF in the late summer to 11,070 AF in the winter. In dry water years (90 percent exceedance probability), monthly inflow ranges from 0 AF in the late summer to 215 AF in early spring (April). Controlled releases from Coyote Reservoir enter Anderson Reservoir as inflows after water losses in the reach of the creek between the two water bodies. The losses consist mainly of evapotranspiration. The losses average 1 to 2 cfs depending on the season. These conditions are the same for both Pre-FOCP and existing conditions. The construction activities do not alter hydrology in the upper portions of the watershed or releases from Coyote Reservoir.

Since the construction of Anderson Dam in 1950, high flows in Coyote Creek have been attenuated by the reservoir and uncontrolled spill release events occur on average every nine years via a surface release spillway, impeding sediment transport and promoting channel incision downstream of the dam. Due to regulated flows, in the Pre-FERC Order Baseline condition, Coyote Creek downstream of Anderson Dam has been mostly perennial, generally with higher summer flows and lower winter flows than would occur if the dam were not in place. During summer months, Valley Water has typically released a combined flow rate of between 20 and 60 cfs into Coyote Creek from Anderson Reservoir and from the CDL. The modeled 50 percent exceedance flows (i.e., a 2-year recurrence interval) in the FCWMZ (POI COYO9) are approximately 50 cfs from May–September. Of the water released downstream of Anderson Dam, approximately 8–9 cfs has been percolating into groundwater in the FCWMZ during the summer months (Valley Water, unpublished data).

Predicted monthly average streamflow for 10–90 percent exceedance probabilities and median streamflow by water year type at POI COYO9 in Coyote Creek downstream of Anderson Reservoir under modeled 2015 (pre-FERC order) conditions. Data are from Valley Water's WEAP model (SEI and Valley Water 2020). Anderson Reservoir Inflow percent exceedance (year) is based on Anderson Reservoir natural inflow (1936–2020).

Table 3.4-4. Predicted monthly average stream flow (CFS) exceedance for Pre-FERC Order conditions at COYO9 generated by the WEAP Model

Source: Unpublished WEAP Model outputs

Under Pre-FERC Order Conditions, during the winter months, Valley Water refills Anderson Reservoir and reduces flows released to Coyote Creek downstream of the dam to store local water that will serve as a cold pool in the summer. Under the Pre-FERC Order Baseline, storm flows are captured by the reservoir and winter peak flows in Coyote Creek are muted—particularly in early winter. While modeled 50 percent exceedance flows in the FCWMZ (POI COYO9) under Pre-FERC Order Baseline remain within a relatively narrow range (37–46 cfs) from

October–April, the modeled daily average flows at this location exhibit considerable fluctuation between about 40 and 200 cfs during this period.

Under Pre-FERC Order Baseline, inter-annual flow variability occurs, with substantial differences in the occurrence of peak flows between dry and wet water years, and with only minor variations in baseflows between years regardless of water year type. Intra-annual flow variability under Pre-FERC Order Baseline is apparent, with peak flows occurring primarily during the wet season, but with little variation in baseflows between the wet and dry season.

Since Anderson Reservoir is to be kept at Deadpool for the duration of FOCP and Project, releases from the reservoir will not be available during the summer months and winter and spring flows will be based on natural precipitation events. Flow is expected to be maintained to at least 10 cfs at gage 5082 during the project. Flow increase may occur during winter periods from precipitation events or increase releases of imported water. From the outlet of Anderson Dam to Gage SF07, less than one mile upstream of the Coyote Percolation Pond, percolation and evaporation can reduce winter flows to around 7 to 10 cfs under existing conditions. Loss of surface flow continues downstream past the Coyote Percolation Pond, at which point flows increase in a downstream direction as a result of groundwater emergence and inflow from Lower Silver Creek and Upper Penitencia Creek.

3.4.1.4 Non-Native Species

Non-native fish species are discussed here because the impact analysis considers whether Project implementation could increase adverse effects that non-native species might have on special status species. Furthermore, with the release of imported water to Coyote Creek, new non-native species may be introduced during the Project. Some non-native species are competitors with or predators on special status fish.

Several non-native species occur within the study area as a result of historical stocking for angling purposes, stocking by anglers for bait fish, incidental transfer through vessels, domestic animals, and other anthropogenic activities. Many of the non-native species present are managed by CDFW as game fish, even though they can have negative impacts on native species. Piscivorous species may prey upon special-status fish or compete for resources, affecting growth and condition factor (Swales 2006). The non-native fish species that occur within the study area are generally more tolerant of warm water than many of the native fish species.

New Zealand mudsnails (*Potamopyrgus antipodarum*) which are non-native and invasive, are also present in the study area in Coyote Creek.

Valley Water monitors for zebra mussels (*Dreissena polymorpha*) and quagga mussels (*Dreissena bugensis*) in Anderson Reservoir but have not detected any to date.

In the Pre-FERC Order Baseline Condition, although the relatively high baseflows year-round promote abundant habitat for special status fish, Yarnell et al. (2015) cite lack of seasonality of baseflows and constant high dry season baseflows promote conditions for non-native species (Kiernan and Moyle 2012) or can lead to an accumulation of silt and reduction in habitat diversity (Moyle and Mount 2007). However, releases from the Dam to provide habitat and flow variability generally supports conditions more favorable for native species.

Under existing conditions and construction the assemblage or distribution of non-native fish species in Coyote Creek is not expected to change. Changes associated with the project will not provide habitat that is more suitable. The Anderson Reservoir drawdown activities could create conditions that may allow for increase access of non-native species to Coyote Creek. Actions taken by Valley Water in FERC-ordered Invasive Species Monitoring and Control Plan during sampling activities and construction related dewatering will help reduce the abundance of non-native species.

Occurrence of Non-Native Fish Species in Anderson Reservoir

In the Pre-FOCP condition, a variety of non-native fish species occurred in Anderson Reservoir including: largemouth bass (*Micropterus salmoides*), red ear sunfish (*Lepomis microlophus*), bluegill (*Lepomis macrochirus*), catfish (*Ictalurus* and *Ameiurus* spp.), common carp (*Cyprinus carpio*), golden shiner (*Notemigonus crysoleucas*), threadfin shad (*Dorosoma petenense*), and inland silverside (*Menidia beryllina*), black crappie (*pomoxis migromaculatus),* white crappie (*Pomoxis annularis*), and koi (Leidy 2007; CDFW 2020; Valley Water 2020b, 2020c; 2023c ~~C. Leal, Pers, Comm. 2023).~~ CDFW has previously managed Anderson and Coyote Reservoirs as a fishery for non-native game fishes, such as largemouth bass, sunfish, black crappie, and catfish. Historically, since at least the 1960’s. CDFW stocked both Anderson and Coyote Reservoirs with a variety of native (rainbow trout) and non-native fish species (largemouth bass, red ear sunfish, bluegill, various catfish species, black crappie, etc.). The last CDFW stocking record that Valley Water was able to locate was from Coyote Reservoir in 2004 and it consisted of rainbow trout. No recent stocking of any fish species occurred in Anderson Reservoir prior to implementation of the FERC Order, as non-native populations appear to be self-sustaining. Coyote Reservoir has not been stocked by CDFW since 2004 and no additional non-native fish have been observed in Coyote Reservoir that are not present in Anderson Reservoir (Valley Water 2020b, 2020c).

Exploratory sampling in Anderson Reservoir using boat-based electrofishing in the spring of 2023, documented the following nonnative species in the reservoir under existing conditions: largemouth bass, common carp, black crappie, threadfin shad, inland silverside, bluegill, and koi. Only one native species, detected in the sampling effort was Sacramento sucker (*Catostomus occidentalis*) (Valley Water 2023c ~~C. Leal Pers. Comm. 2023~~).

Occurrence of Non-Native Fish Species in Coyote Creek downstream of Anderson Dam

The first non-native species in Coyote Creek appeared prior to construction of Anderson Dam in 1941 (Leidy 2007). Post-Anderson Dam construction, the seven non-native species known to occur in Coyote Creek, previously only observed downstream of Coyote Percolation Dam, were documented upstream of Coyote Percolation Dam, likely a result of migration from Anderson Reservoir (Buchan and Randall 2003). Currently, spotted bass, largemouth bass, green sunfish, bluegill, black crappie, channel catfish, common carp, golden shiner, red shiner (*Cyprinella lutrensis*), brown bullhead (*Ameiurus nebulosus*), yellow bullhead (*Ameiurus natalis*), western mosquitofish (*Gambusia affinis*), fathead minnow (*Pimephales promelas*), threadfin shad, and inland silverside are known to occur in Coyote Creek downstream of Anderson Reservoir (Leidy 2007; CDFW 2020; Valley Water 2008b, Valley Water, unpubl. data).

Since implementation of the FERC Order under existing conditions, non-native species persist in Coyote Creek downstream of Anderson Dam. Electrofishing surveys in the CWMZ by Valley Water have captured largemouth bass, spotted bass, bluegill, green sunfish, threadfin shad, inland silverside, and common carp. A fyke trap at the outlet of Anderson Dam deployed during late September through late November 2020 captured non-native largemouth bass, black crappie, bluegill, common carp, threadfin shad, and inland silversides during the reservoir drawdown (Valley Water 2021d ~~2021c~~). Other non-native species such as channel catfish have been documented on the Vaki Riverwatcher (Valley Water 2020e ~~2020d~~). Slow water refugia in Coyote Creek, such as Ogier and Coyote Percolation Ponds, continue to provide optimal habitat for warmwater non-native fishes which may prey upon or compete for habitat with native fishes.

In addition, New Zealand mud snails have recently been documented in Coyote Creek downstream of Anderson Dam (Valley Water unpublished data, USGS 2023).

Occurrence of Non-Native Fish Species in Upper Penitencia Creek

In the Pre-FERC Order Conditions, few non-native fish are documented and abundance is low in Upper Penitencia Creek; however, golden shiner, goldfish (*Carassius auratus*) and largemouth bass were documented during previous surveys (Valley Water 2008a, 2008b, 2019~~a~~). Under existing conditions, the abundance, assemblage, and distribution of non-native fish species in Upper Penitencia Creek is not expected change. Actions associated with the project will take proper precautions to avoid the transfer of non-native species. ~~[Suggest insert any post-FERC Order existing conditions data here, or state no expected changes in Existing condition]~~

3.4.2 Regulatory Setting

This section summarizes the federal and State laws, regulations, policies, and plans pertinent to the evaluation of the Project's impacts on aquatic biological resources.

3.4.2.1 Federal Laws, Regulations, and Policies

Clean Water Act

See Section 3.14, *Water Quality,* regarding Sections 401 and 404 of the Clean Water Act (CWA).

Endangered Species Act

The federal ESA (16 USC Section 1531 et seq.) protects fish and wildlife species that are listed as threatened or endangered and designated critical habitats. *Endangered* refers to species, subspecies, or distinct population segments that are in danger of extinction in all or a significant portion of their range. *Threatened* refers to species, subspecies, or distinct population segments that are considered likely to become endangered in the future. The ESA prohibits unauthorized "take" of any fish or wildlife species listed by the federal government as endangered or threatened (*take* is defined as harassment, harm, pursuit, hunting, shooting, wounding, killing, trapping, capture, or collection, or the attempt to engage in any such conduct). The ESA is administered by the USFWS for terrestrial and freshwater species and by the National Oceanographic and Atmospheric Administration's NMFS for marine species and anadromous fishes.

USFWS and NMFS can authorize incidental take through federal consultation under Section 7 of the ESA or through an incidental take permit and HCP under Section10(a)(1)(B). CCC steelhead (*Oncorhynchus mykiss*) and southern green sturgeon (*Acipenser medirostris*) populations are fish species that are protected under the Endangered Species Act that may occur in the study area and are undergoing Section 7 consultation between the FERC, USACE, and NMFS. Longfin Smelt, which also may occur in the study area, are proposed for listing as endangered by USFWS and are undergoing Section 7 consultation between FERC and USACE and USFWS. The VHP is an HCP that is relevant to the Project. While it provides incidental take coverage for several terrestrial species (see Terrestrial Biological Resources), it does not provide incidental take coverage for fish species. However, several VHP conditions benefit native fish species in Coyote Creek.

The ESA also requires that USFWS and NMFS designate critical habitat for the listed species they manage. The ESA defines critical habitat as "the specific areas within the geographical area occupied by the species, at the time it is listed, on which are found those physical or biological features (I) essential to the conservation of the species and (II) which may require special management considerations or protection; and specific areas outside the geographical area occupied by the species at the time it is listed that are determined by the Secretary to be essential for the conservation of the species." The study area includes designated critical habitat for central California coast steelhead and green sturgeon.

With respect to the Project, ESA Section 7 will be used to address any incidental take and adverse modifications of critical habitat for listed fish species, including steelhead and green sturgeon, and, if listed, longfin smelt, because FERC and USACE must consult with NMFS and USFWS under ESA Section 7 before issuing authorizations for the construction activities necessary to implement the Project.

Magnuson-Stevens Fishery Conservation and Management Act

The Magnuson Stevens Fishery Conservation and Management Act, as amended (16 USC Section 1801 et seq.), requires that all federal agencies consult with NMFS on activities or proposed activities authorized, funded, or undertaken by that agency which may adversely affect essential fish habitat (EFH). EFH is identified for anadromous Pacific salmon stocks and coastal pelagic fish managed by the PFMC under the Pacific Coast Salmon Fishery Management Plan (FMP). These managed salmon include most of the Chinook salmon (*Oncorhynchus tshawytscha*) stocks from Washington, Oregon, Idaho, and California. The geographic extent of freshwater EFH is specifically identified in the FMP as all water bodies currently or historically occupied by PFMC-managed salmon in Washington, Oregon, Idaho, and California. The study area includes EFH in Coyote Creek for Chinook salmon and Coho salmon (*Oncorhynchus kisutch*) and South San Francisco Bay for groundfish and coastal pelagic species. Consultation under this Act was combined with ESA Section 7 consultation for the Project.

3.4.2.2 State Laws, Regulations, and Policies

California Endangered Species Act

CESA (Fish and Game Code section 2050 et seq.) protects wildlife and plants listed as *threatened* and *endangered* by the California Fish and Game Commission, as well as species identified as candidates for such listing. It is administered by the CDFW. CESA requires state agencies to conserve threatened and endangered species (section 2055) and thus restricts all persons from take of listed species except under certain circumstances. CESA defines *take* as any action or attempt to "hunt, pursue, catch, capture, or kill". The state definition does not include "harm" or "harass" as the federal definition does. As a result, the threshold for take under CESA is typically higher than that under the FESA.

Under certain circumstances, CDFW may authorize limited take, except for species designated as fully protected unless certain conditions are met (see discussion of fully protected species ~~under California Fish and Game Code below~~ in the regulatory setting for Section 3.5, *Biological Resources—Wildlife and Terrestrial Resources*). The requirements for an application for an incidental take permit under CESA are described in section 2081 of the Fish and Game Code and in final adopted regulations for implementing sections 2080 and 2081.

Longfin smelt are a state threatened species that occur in the study area. In the event that *take* (as defined under CESA) of longfin smelt might occur as a result of adverse impacts of the otherwise lawful implementation of the Project (which is unlikely), Valley Water may obtain an incidental take permit under CESA section 2081 to authorize that take. Central Valley fall-run Chinook salmon, Pacific lamprey, Sacramento hitch, southern coastal roach, white sturgeon, and riffle sculpin, although not listed under CESA, are designated Species of Special Concern by CDFW.

Porter-Cologne Water Quality Control Act

See Section 3.14, *Water Quality,* regarding the Porter-Cologne Water Quality Control Act.

Water Quality Control Plan for the San Francisco Bay Basin

The San Francisco Bay RWQCB developed, adopted, updated, and currently implements the San Francisco Bay Basin (Region 2) Water Quality Control Plan (Basin Plan) (San Francisco Bay RWQCB 2019).

The Basin Plan establishes water quality standards that protect the biological, chemical, fisheries and recreational quality of waters of the state, as required by the federal CWA and the Porter-Cologne Water Quality Control Act. Water quality standards include two components: designated beneficial uses of water, and water quality objectives to protect those uses. Related to fisheries, existing beneficial uses designated for study area water bodies include cold freshwater habitat, warm freshwater habitat, fish migration, preservation of rare and endangered species, and fish spawning (San Francisco Bay RWQCB 2019) (**Table 3.4-5)**.

In making a decision whether to grant a Water Quality Certification for the Project, which involves FERC authorization and issuance of a section 404 permit by the USACE, the SWRCB considers whether the federally-regulated activity will comply with the water quality standards established in the Basin Plan., including both water quality objectives and beneficial uses.

Table 3.4-5. Aquatic Life Beneficial Uses in the Study Area defined by the San Francisco Bay Regional Water Quality Control Board Basin Plan 2019

Waterbody	Commercial and Sport Fishing	Cold Freshwater Habitat	Estuary Habitat	Fish Migration	Preservation of Rare and Endangered Species	Fish Spawning	Warm Freshwater Habitat

Source: San Francisco Bay Regional Water Quality Control Board Basin Plan 2019)

Key: X = existing beneficial use

N/A = not applicable

For additional information about the Basin Plan, see Section 3.14, *Water Quality*.

Fish and Game Code Section 1600 et seq. – Lake and Streambed Alteration Program

Pursuant to Fish and Game Code section 1600 et seq., CDFW regulates any project proposed by any person that will "substantially divert or obstruct the natural flow or substantially change the bed, channel, or bank of any river, stream, or lake designated by the department, or use any material from the streambeds". Regarding the definition of a river or stream or lake, at a minimum, CDFW claims jurisdiction over the water body's bed and bank. Where riparian habitat is present, the outer edge of riparian vegetation is generally used as the line of demarcation between riparian and upland habitats. Fish and Game Code section 1602 requires an entity to notify CDFW of any proposed activity that may modify a river, stream, or lake. If CDFW determines that proposed activities may substantially adversely affect fish and wildlife resources, an LSAA must be prepared. The LSAA sets reasonable conditions necessary to protect fish and wildlife. The applicant may then proceed with the activity in accordance with the final LSAA.

Several Project components would result in impacts to the bed and banks of streams regulated by CDFW under Fish and Game Code section 1600 et seq. Valley Water will apply for and obtain a Lake and Streambed Alteration Agreement before impacting CDFW-regulated stream and riparian habitats.

Fish and Game Code Sections 5901 and 5937

Section 5901 of the Fish and Game Code states that it is unlawful to construct or maintain any device in a stream which prevents, impedes, or tends to impede the passing of fish upstream and downstream. Fish and Game Code section 5937 requires dam owners to allow sufficient water to pass to keep any fish existing below the dam in good condition. These sections of the code are relevant to the Project because they include operations of dams, retrofits of a dam, in-channel Conservation Measure construction, and long-term flow operations.

Natural Community Conservation Planning Act

The NCCP Act identified a need for "broad-based planning to provide for effective protection and conservation of the state's wildlife heritage while continuing to allow appropriate development and growth" (Fish and Game Code section 2801[b]). The Act describes the use of natural community conservation planning as a tool to protect species diversity and reduce conflict. An NCCP is a conservation plan that focuses on the conservation of natural communities at a landscape level. It provides a means of complying with the NCCP Act (Fish and Game Code section 2835) and securing CESA take authorization at the state level in exchange for conservation of natural communities. The VHP discussed below is both an NCCP and an HCP that provides for the conservation and protection of, as well as authorized incidental take of 18 "covered species," including California tiger salamander, California red-legged frog, foothill yellow-legged frog, and western pond turtle, all which are addressed in the Terrestrial Biology section of this EIR.

The primary objective of the NCCP program is to conserve natural communities at the ecosystem scale and contribute to species' recovery while accommodating compatible, lawfully adopted land uses and authorizing incidental take associated with those land uses. To be approved by CDFW, an NCCP must provide for the conservation of species and protection and management of natural communities, as well as listed species associated with those communities, in perpetuity within the area covered by permits.

3.4.2.3 Regional and Local Laws, Regulations, and Policies

Santa Clara Valley Habitat ~~Conservation~~ Plan

The VHP (ICF 2012) provides a framework for promoting the protection and recovery of natural resources, including terrestrial special-status species, while streamlining the state- and federally listed species permitting processes for planned development, infrastructure, and maintenance activities. The VHP allows the County, Valley Water, the Santa Clara Valley Transportation Authority (VTA), and the cities of Gilroy, Morgan Hill, and San José (collectively, the Local Partners or Permittees) to receive permits authorizing incidental take of listed species covered by the plan for activities and projects they conduct and those under their jurisdiction. The Santa Clara Valley Open Space Authority also contributed to the VHP preparation. The VHP protects, enhances, and restores natural resources in specific areas of the county and contribute to the recovery of endangered species. Rather than separately permitting and mitigating individual projects, the VHP evaluates natural-resource impacts and mitigation requirements, including impacts and mitigation requirements for aquatic resources, comprehensively in a way that is more efficient and effective for at-risk species and their essential habitats.

The VHP was developed with and approved by the USFWS and CDFW and in consultation with stakeholder groups and the general public. The USFWS has issued the Permittees a 50-year permit that authorizes incidental take of covered listed species under the federal ESA, while CDFW has issued a 50-year permit that authorizes take of all covered listed species under the NCCPA. This approach allows the Permittees to streamline future mitigation requirements, including those for aquatic and riparian species, into one comprehensive program. In addition to obtaining take authorization for each participating agency's respective activities, the cities and County are able to extend take authorization to project applicants under their jurisdiction.

USFWS and CDFW also have provided assurances to the Permittees that no further commitments of funds, land, or water would be required to address impacts on covered species beyond those described in the Plan to address changed circumstances. In addition to strengthening local control over land use and species protection, the Plan provides a more efficient process for protecting natural resources by creating new habitat reserves that will be larger in scale, more ecologically valuable, and easier to manage than the individual mitigation sites created under the current approach.

The VHP and associated documents have been approved and adopted by the six Local Partners (the cities of Gilroy, Morgan Hill and San José, the County, VTA, and Valley Water).

Although the VHP does not provide take authorization for fish species, it does identify particular conservation objectives for aquatic and riparian resources, and several VHP conditions would avoid and minimize impacts on aquatic habitat and species. Consequently, on January 28, 2021the USACE renewed and re-issued Regional General Permit 18 (RGP 18)[5] for impacts to USACE jurisdictional waters of the United States resulting from projects constituting covered

[5] USACE first issued RGP 18 November 18, 2015, then renewed and reissued the regional permit on January 28, 2021.

activities pursuant to VHP. In issuing RGP 18, USACE determined that the VHP establishes a watershed plan sufficient and appropriate under federal compensatory mitigation regulations to assure that project proponents implement a watershed approach to the provision avoidance, minimization and mitigation to compensate for the loss of aquatic resources within the VHP Plan Area resulting from discharges of dredged and fill material. USACE further determined that mitigation consisting of payment of VHP fees to VHA for implementation of aquatic habitat restoration, creation, enhancement and preservation fully complies with the federal Clean Water Act Mitigation Rule (33 CFR Part 332) (“Federal Mitigation Rule”). *Compensatory Mitigation Strategy for Santa Clara Valley Habitat Plan Regional General Permit Prior to Approval of a Proposed In-Lieu Fee Program* (USACE January 15, 2016) (“RGP Mitigation Strategy”). Based on that comprehensive analysis, USACE determined that permit applicants providing mitigation for covered activity impacts on aquatic habitats via payment of VHP fees would comply with all requirements of the Federal Mitigation Rule, including requirements designed to implement the state and federal “no net loss” of wetlands policy. In fact, USACE determined that providing mitigation by payment of VHP fees for impacts to aquatic habitat types “would provide a ‘net gain’ of aquatic resource functions and acreage.”

Similarly, the California Porter Cologne Water Quality Control Act authorizes the provision of permittee-responsible mitigation to offset impacts to aquatic habitat types within the VHP Plan Area by payment of VHP fees. Pursuant to Section V of the SWRCB’s Procedures for Discharge of Dredge or Fill Material to Waters of the State (April 2, 2019) (the “Procedures”), the VHP, which was approved by USFWS and CDFW before December 31, 2020, and includes biological goals for wetland and aquatic resources, “shall be used by the permitting authority as a watershed plan for such aquatic resources”. The VHP therefore sets a framework for compensatory mitigation determinations in the issuance of 401 certifications for impacts on aquatic resources. The Procedures also incorporate the Federal Mitigation Rule almost verbatim into Appendix 1, Subpart J of the Regulations. For all the reasons set forth in the RGP Mitigation Strategy, payment of VHP fees to VHA for VHA’s use to restore, create, enhance and preserve aquatic habitat types as described in the VHP may constitute acceptable compensatory mitigation for impacts to aquatic resources under Subpart J, Section 230.93(b)(4) of those regulations.

Safe, Clean Water, and Natural Flood Protection Program (Measure B – the Safe, Clean Water and Natural Flood Protection Program)

The Safe, Clean Water, and Natural Flood Protection Program is designed with five priorities, including: (1) ensure a safe, reliable water supply; (2) reduce toxins, hazards, and contaminants; (3) protect the water supply from earthquakes and natural disasters; (4) restore wildlife habitat and provide open space; and (5) provide flood protection. Valley Water prepares an annual report providing a progress update for each of these program priorities, along with fiscal year accomplishments. This program benefits aquatic resources through restoration activities, monitoring, and preserving natural lands.

Water Resources Protection Ordinance of the Santa Clara Valley Water District (as amended by Ordinance 08-1)

The Water Resource Protection Ordinance (as amended by Ordinance 08-1) was adopted by Valley Water to help implement the Guidelines and Standards for Land Use near Streams (Santa Clara Valley Water Resources Protection Collaborative 2006). The ordinance is intended to protect the water resources managed by Valley Water and provides a set of model guidelines and standards for land use along stream corridors, and it regulates access to and use of Valley Water's facilities and easements. The ordinance specifies the project review and permitting process for projects located on and/or require use of ~~within 50 feet of a creek or waterway, or within 50 feet of a~~ Valley Water-owned property or easement. The Water Resources Protection Manual provides guidance for complying with the ordinance. This ordinance protects aquatic resources and guides land use activities to reduce impacts to aquatic habitats.

Valley Water Stream Maintenance Program

Under the SMP, work occurs annually to improve the environment, reduce the risk of flooding, and keep communities safe. Work under the SMP can improve fish habitat (Horizon Water and Environment 2011).

Santa Clara County General Plan

The Resource Conservation Element of the Santa Clara County General Plan (1994) includes the following conservation and management strategies that are relevant to fisheries resources:

- Reduce Non-Point Source Pollution
- Restore Wetlands, Riparian Areas, and Other Habitats That Improve Bay Water Quality
- Prepare and Implement Comprehensive Watershed Management Plans
- Improve Current Knowledge and Awareness of Habitats and Natural Areas
- Protect the Biological Integrity of Critical Habitat Areas

City of Morgan Hill General Plan

The City of Morgan Hill General Plan (2017 ~~2016~~) contains the following goals, policies, and actions that are relevant to fisheries resources and the Project Area:

Natural Resources and Environment (NRE)

Goal NRE-6: Protection of native plants, animals, and sensitive habitats.

Policy NRE-6.1: Natural State of Habitat. Preserve all fish and wildlife habitats in their natural state whenever possible. Consider development impacts upon wildlife and utilize actions to mitigate those environmental impacts.

Policy NRE-6.2: Habitat Conservation Plan. Support the implementation of the Santa Clara Valley Habitat Plan to protect wildlife, rare and endangered plants and animals, and sensitive habitats from loss and destruction.

Policy NRE-6.4: Tree Preservation and Protection. Preserve and protect mature, healthy trees whenever feasible, particularly native trees, historically significant trees, and other trees which are of significant size or of significant aesthetic value to the immediate vicinity or to the community as a whole.

Policy NRE-6.5: Soil and Erosion. Require development to be designed to conserve soil and avoid erosion. (South County Joint Area Plan 13.06)

Policy NRE-6.6: Use of Native Plants. Encourage use of native plants, especially drought-resistant species, in landscaping.

Policy NRE-6.7: Habitat Protection and Enhancement. Encourage the protection, restoration, and enhancement of remaining native grasslands, oak woodlands, marshlands, and riparian habitat.

Action NRE-6.A: Standard Measures for Construction Activities. Develop a set of standard measures requiring construction activities to avoid disturbance to natural features to the extent feasible.

Envision San José 2040 General Plan

The *City of San Jose General Plan* (2023 ~~2011~~) contains the following goals and policies relevant to biological resources and the Project Area:

Goal ER-4: Preserve, manage, and restore habitat suitable for special-status species, including threatened and endangered species.

Policy ER-4.1: Preserve and restore, to the greatest extent feasible, habitat areas that support special-status species. Avoid development in such habitats unless no feasible alternatives exist, and mitigation is provided of equivalent value.

Goal ER-5: Protect migratory birds from injury or mortality.

Policy ER-6.6: Encourage the use of native plants in the landscaping of developed areas adjacent to natural lands.

3.4.3 Methodology and Approach to Impact Analysis

The following impact analysis evaluates impacts on fisheries resources that would occur as a result of the following activities:

- Seismic Retrofit Construction (construction activities and instream flows during construction resulting from construction phase dewatering pursuant to implementation of the Project Construction Period Reservoir Operations and Drawdown Plan, including the two-stage reservoir dewatering plan and flow related Conservation Measures),
- Conservation Measures Construction
- Construction Monitoring
- Post-Construction Anderson Dam Facilities ~~Instream Flows~~ Operations and Maintenance
- ~~Anderson Dam and~~ Post-Construction Conservation Measures ~~Post-Construction~~ Operations and Maintenance
- Post-Construction Project and FAHCE Adaptive Management

For each of these aspects of the Project, impacts were assessed for the Seismic Retrofit Project Area, the Conservation Measures Project Area, downstream portions of the study area to the confluence of Alviso Slough in South San Francisco Bay, as well as the tributary Upper Penitencia Creek, aided by the evaluation of modeling results for baseline, construction phase and post-construction phase depth, temperature, velocity and other in-stream conditions at POIs within Coyote Creek and Upper Penitencia. The analysis of impacts on fisheries resources is also based on the results of field surveys, habitat assessments, and desktop analyses conducted for fisheries resources and on the baseline conditions with respect to presence/absence, locations of occurrence, and abundance/extent of biological resources, as well as the life-history traits and timing of fish species that influence how they may be impacted by Project activities.

Impacts on fisheries resources were first evaluated qualitatively to describe how Project activities may adversely impact fisheries resources, and then, where applicable, quantitative data and/or modeling were available to inform the analysis. Impacts were assessed relative to baseline conditions. For the purpose of the analysis of Seismic Retrofit Construction and Conservation Measures Construction, baseline conditions are the existing conditions present at the time of EIR preparation as modified by FOCP implementation. However, to best assess effects on fisheries, instream flows during construction impacts are assessed relative to the Pre-FERC Order Baseline representing normal, historical flow conditions within the study area, as well as relative to the ~~Post-FERC Order Existing Conditions~~ Existing Conditions baseline as modified by FOCP, to fully evaluate the effects of construction phase dewatering, including the implementation of the Project Construction Operations Technical memorandum . The effects of post-construction operations were analyzed relative both to the Pre FERC Order Baseline and the Future Baseline to assure an understanding of effects as compared to “business as normal” operations prior to the FERC Order and what would have been “business as normal” operations after completion of seismic retrofit.

The impact evaluation also considered whether adverse impacts or benefits to instream flows or the in-channel environment would be “short-term” or “long-term,” with short-term adverse impacts occurring temporarily for a fixed amount of time and long-term impacts (or often benefits) continuing into the future after construction of the Project.

After qualitative and, where applicable, quantitative analysis of an impact was performed, the impact was then evaluated with the application of Valley Water BMPs (**Table 3.4-6**)**,** VHP Conditions (**Table 3.4-7**), and applicable AMMs (**Table 3.4-8**). A determination was then made regarding whether the impact was significant (and thus requires mitigation). For impacts that would remain significant even with implementation of BMPs, VHP conditions, and VHP AMMs, feasible mitigation measures are identified, and the significance of the impacts were then re-evaluated to determine if mitigation measures would reduce impacts to a less-than-significant level.

The following sections provide additional detail for how each of the Project components was evaluated—Seismic Retrofit construction (both construction activities and instream flows during construction), Conservation Measures construction, construction monitoring, and post-construction operations, maintenance, and monitoring (including Project and FAHCE adaptive management)—for impacts on fisheries resources.

Table 3.4-6. Summary of Valley Water BMPs to be Implemented for Seismic Retrofit Construction, Conservation Measure Construction, Maintenance, and Adaptive Management[6]

Table 3.4-8. Summary of Santa Clara Valley Habitat Plan-Required Aquatic Avoidance and Minimization Measures Related to Conditions 3, 4, 5, and 11 that are Applicable to Each Project Impact on Fisheries Resources

ID	Avoidance and Minimization Measure (AMM)	Fisheries Resources (FR) Impact								
		FR-1a: Steelhead	FR-1b: Chinook	FR-1c: Lamprey	FR-1d: Hitch	FR-1e: Roach	FR-1f: Smelt	FR-1g: W. Sturgeon	FR-1h: G. Sturgeon	FR-1i: Riffle Sculpin
General										
2	Reduce stream pollution by removing pollutants from surface runoff before the polluted surface runoff reaches local streams.	X	x	x	x	x	x	x	x	
3	Maintain the current hydrograph and, to the extent possible, restore the hydrograph to more closely resemble predevelopment conditions.	X	x	x	x	x	x	x	x	
4	Reduce the potential for scour at stormwater outlets to streams by controlling the rate of flow into the streams	x	x	x	x	x				
5	Invasive plant species removed during maintenance will be handled and disposed of in such a manner as to prevent further spread of the invasive species	x	x	x	x	x				
6	Activities in the active (i.e., flowing) channel will be avoided, or AMMs in this table will be applied.	X	x	x	x	x				
7	Personnel shall prevent the accidental release of chemicals, fuels, lubricants, and non-storm drainage water into channels.	X	x	x	x	x	x	x	x	
8	Spill prevention kits shall always be in close proximity when using hazardous materials (e.g., crew trucks and other logical locations).	X	x	x	x	x	x	x	x	

ID	Avoidance and Minimization Measure (AMM)	Fisheries Resources (FR) Impact								
		FR-1a: Steelhead	FR-1b: Chinook	FR-1c: Lamprey	FR-1d: Hitch	FR-1e: Roach	FR-1f: Smelt	FR-1g: W. Sturgeon	FR-1h: G. Sturgeon	FR-1i: Riffle Sculpin
9	Personnel shall implement measures to ensure that hazardous materials are properly handled and the quality of water resources is protected by all reasonable means when removing sediments from streams	x	x	x	x	x	x	x	x	
11	Vehicles shall be washed at approved areas. No washing of vehicles shall occur at job sites.	X	x	x	x	x	x	x	x	x
12	No equipment servicing shall be done in the stream channel or immediate floodplain unless equipment cannot be readily relocated.	X	x	x	x	x	x	x	x	
13	Personnel shall use the appropriate equipment for the job that minimizes disturbance to the stream bottom.	X	X	x	x	x				
14	If high groundwater is present in a work area, pump it out of the work site carefully to remove sediment prior to the water re-entering a creek.	X	x	x	x	x				
15	Implement native aquatic vertebrate relocation plan when ecologically appropriate as determined by a qualified biologist.	X	x	x	x	x				
17	Install cofferdams both upstream and downstream not more than 100 feet from the extent of the work areas.	X	x	x	x	X				
18	Small in-channel berms that deflect water to one side of the channel may be constructed of channel material in channels with low flows.	X	x	x	x	X				
20	Diversions shall maintain ambient stream flows below the diversion, with no reduction or degradation.	X	x	x	x	x				

ID	Avoidance and Minimization Measure (AMM)	Fisheries Resources (FR) Impact								
		FR-1a: Steelhead	FR-1b: Chinook	FR-1c: Lamprey	FR-1d: Hitch	FR-1e: Roach	FR-1f: Smelt	FR-1g: W. Sturgeon	FR-1h: G. Sturgeon	FR-1i: Riffle Sculpin
21	If stream bed design changes are not part of the project, the stream bed will be returned to as close to pre-project condition as appropriate.	X	x	x	x	x				
22	Remove all temporary diversion structures and the supportive material no more than 48 hours after work is completed.	X	x	x	x	x				
23	Temporary fills, such as for access ramps, diversion structures, or cofferdams, shall be completely removed upon finishing the work.	X	x	x	x	x				
24	To prevent increases in temperature and decreases in dissolved oxygen, properly size bypass pipes or use a low-flow channel.	X	x	x	x	X				
25	Diversions shall maintain fish passage under specified project conditions.	X	x	x	x	X				
26	Any sediment removed from a project site shall be stored and transported in a manner that minimizes water quality impacts.	X	x	x	x	x	x	x	X	
28	Where practical, the removed sediments and gravels will be re-used	x	x	x	x	x				
29	Existing native vegetation shall be retained by removing only as much vegetation as necessary to accommodate the trail clearing width. Maintenance roads should be used to avoid effects on riparian corridors.	X	x	x	x	x				
30	Vegetation control and removal in channels, on stream banks, and along levees and maintenance roads shall be limited.	X	x	x	x	X				
31	When conducting vegetation management, retain as much understory brush and as many trees as feasible.	X	x	x	x	x				

ID	Avoidance and Minimization Measure (AMM)	Fisheries Resources (FR) Impact								
		FR-1a: Steelhead	FR-1b: Chinook	FR-1c: Lamprey	FR-1d: Hitch	FR-1e: Roach	FR-1f: Smelt	FR-1g: W. Sturgeon	FR-1h: G. Sturgeon	FR-1i: Riffle Sculpin
32	The top of the bank shall be protected by leaving vegetation in place to the maximum extent possible.	X	x	x	x	x				
33	Regional Board objectives for temperature change in receiving waters shall not be exceeded.	X	x	x	x	x				
Project Design										
34	Use the minimum amount of impermeable surface (building footprint, paved driveway, etc.) practicable.	X	x	x	x	x				
35	Use pervious materials, such as gravel or turf pavers, in place of asphalt or concrete to the extent practicable.	X	x	x	x	x				
36	Use flow control structures such as swales, retention/detention areas, and/or cisterns to maintain the existing (pre-Project) peak runoff.	X	x	x	x	x				
38	Use flow dissipaters at runoff inlets (e.g., culvert drop-inlets) to reduce the possibility of channel scour at the point of flow entry.	X	x	x	x	x				
39	Minimize alterations to existing contours and slopes, including grading the minimum area necessary.	X	x	x	x	x				
40	Maintain native shrubs, trees, and groundcover whenever possible and revegetate disturbed areas with local native or non-invasive plants.	X	x	x	x	x				

ID	Avoidance and Minimization Measure (AMM)	Fisheries Resources (FR) Impact								
		FR-1a: Steelhead	FR-1b: Chinook	FR-1c: Lamprey	FR-1d: Hitch	FR-1e: Roach	FR-1f: Smelt	FR-1g: W. Sturgeon	FR-1h: G. Sturgeon	FR-1i: Riffle Sculpin
41	Combine flow-control with flood control and/or treatment facilities in the form of detention/retention basins, ponds, and/or constructed wetlands.	X	x	x	x	x				
42	Use flow-control structures, permeable pavement, cisterns, and other methods to ensure no change in peak runoff.	X	x	x	x	x				
43	Assess site conditions to determine if designs such as bioengineered bank treatments with live vegetation can be successfully utilized.	X	x	x	x	X				
44	Maintain natural stream characteristics, such as riffle-pool sequences, riparian canopy, sinuosity, floodplain, and a natural channel bed.	X	x	x	x	x				
45	Stream crossings shall incorporate a free-span bridge unless infeasible due to engineering or cost constraints or unsuitable based on minimal size of stream. If a bridge design cannot free-span a stream, bridge piers and footings will be designed to have minimum impact on the stream.	X	x	x	x	x				
49	The project or activity must be designed to avoid the removal of riparian vegetation, if feasible.	X	x	x	x	x				
51	All projects will be conducted in conformance with applicable County and/or city drainage policies.	X	x	x	x	x	x	x	x	
53	When possible, maintain a vegetated buffer strip between staging or excavation areas and receiving waters.	X	x	x	x	x				

ID	Avoidance and Minimization Measure (AMM)	Fisheries Resources (FR) Impact								
		FR-1a: Steelhead	FR-1b: Chinook	FR-1c: Lamprey	FR-1d: Hitch	FR-1e: Roach	FR-1f: Smelt	FR-1g: W. Sturgeon	FR-1h: G. Sturgeon	FR-1i: Riffle Sculpin
54	Outside of the construction footprint, maintain deep pools within stream reaches as refugia for fish and wildlife.	X	x	x	x	x				
55	For stream maintenance projects that result in alteration of the stream bed during project implementation, its low-flow channel shall be returned to its approximate prior location with appropriate depth for fish passage without creating a potential future bank erosion problem.	X	x	x	x	x				
56	Bank stabilization site design shall consider hydraulic effects immediately upstream and downstream of the work area.	X	x	x	x	x				
58	Use existing access routes/levee roads to minimize impacts of new construction in special-status species habitats and riparian zones.	X	x	x	x	x	x	x	x	x
61	Minimize ground disturbance to the smallest area feasible.	X	x	x	x	x				
62	Use existing roads for access and disturbed area for staging as site constraints allow.	X	x	x	x	x				
63	Prepare and implement sediment erosion control plans.	X	x	x	x	x	x	x	x	
64	No winter grading shall occur unless approved by City Engineer and specific erosion control measures are incorporated.	X	x	x	x	x	x	x	x	
65	Control exposed soil by stabilizing slopes (e.g., with erosion control blankets) and protecting channels.	X	x	x	x	x	x	x	x	
66	Control sediment runoff using sandbag barriers or straw wattles.	X	x	x	x	x	x	x	x	

ID	Avoidance and Minimization Measure (AMM)	Fisheries Resources (FR) Impact								
		FR-1a: Steelhead	**FR-1b: Chinook**	**FR-1c: Lamprey**	**FR-1d: Hitch**	**FR-1e: Roach**	**FR-1f: Smelt**	**FR-1g: W. Sturgeon**	**FR-1h: G. Sturgeon**	**FR-1i: Riffle Sculpin**
67	No stockpiling or placement of erodible materials shall occur in waterways or along areas of natural stormwater flow.	X	x	x	x	x	x	x	x	
68	Stabilize stockpiled soil with geotextile or plastic covers.	X	x	x	x	x	x	x	x	
69	Maintain construction activities within a defined project area to reduce the amount of disturbed area.	X	x	x	x	x				
70	Only clear/prepare land which will be actively under construction in the near term.	X	x	x	x	x				
71	Preserve existing vegetation to the extent possible.	X	x	x	x	x	x	x	x	x
72	Equipment storage, fueling, and staging areas will be sited on disturbed areas or non-sensitive habitat outside of a stream channel.	X	x	x	x	x	x	x	x	
73	Avoid wet season construction.	X	x	x	x	x				
74	Stabilize site ingress/egress locations.	X	x	x	x	x				
75	Dispose of all construction waste in designated areas and prevent stormwater from flowing onto or off of these areas.	X	x	x	x	x	x	x	x	
76	Prevent spills and clean up spilled materials.	X	x	x	x	x	x	x	x	x
78	In-stream projects occurring while the stream is flowing must use appropriate measures to protect water quality and native aquatic species.	X	x	x	x	x	x	x	x	x

ID	Avoidance and Minimization Measure (AMM)	Fisheries Resources (FR) Impact								
		FR-1a: Steelhead	FR-1b: Chinook	FR-1c: Lamprey	FR-1d: Hitch	FR-1e: Roach	FR-1f: Smelt	FR-1g: W. Sturgeon	FR-1h: G. Sturgeon	FR-1i: Riffle Sculpin
80	All personnel working in or adjacent to the stream setback will be trained by a qualified biologist in AMMs.	X	x	x	x	x	x	x	x	x
83	Sediments will be stored and transported in a manner that minimizes water quality impacts.	X	x	x	x	x				
84	Appropriate erosion control measures (e.g., fiber rolls, filter fences, vegetative buffer strips) will be used on site.	X	x	x	x	x				
87	Vehicles operated within and adjacent to streams will be checked and maintained daily to prevent leaks.	X	x	x	x	x				
88	Vehicles and equipment will be parked on pavement, existing roads, and previously disturbed areas.	X	x	x	x	x	x	x	x	x
90	All trash will be removed from the site daily to avoid attracting potential predators to the site.	X	x	x	x	x	x	x	x	x
91	To prevent the spread of exotic species and reduce the loss of natives, aquatic species will be netted; natives will be released, exotics removed.	X	x	x	x	x				x
92	To minimize the spread of pathogens, all staff working in aquatic systems will adhere to equipment decontamination guidelines.	X	x	x	x	x	x	x	x	x
94	Personnel shall use existing access ramps and roads if available.	X	x	x	x	x	x	x	x	x
97	Erosion control measures shall be in place at all times during construction.	X	x	x	x	x				

ID	Avoidance and Minimization Measure (AMM)	Fisheries Resources (FR) Impact								
		FR-1a: Steelhead	FR-1b: Chinook	FR-1c: Lamprey	FR-1d: Hitch	FR-1e: Roach	FR-1f: Smelt	FR-1g: W. Sturgeon	FR-1h: G. Sturgeon	FR-1i: Riffle Sculpin
98	When needed, utilize in-stream grade control structures to control channel scour, sediment routing, and headwall cutting.	X	x	x	x	x				
Post-Construction										
100	Potential contaminating materials must be stored in covered storage areas or secondary containment impervious to leaks and spills.	X	x	x	x	x	x	x	x	
101	Runoff pathways shall be free of trash containers or trash storage areas. Trash storage areas shall be screened or walled.	X	x	x	x	x	x	x	x	x
102	Immediately after project completion and before close of seasonal work window, stabilize all exposed soil.	X	x	x	x	x				
103	All disturbed soils will be revegetated with native plants and/or grasses or sterile non-native species.	X	x	x	x	x				
104	Measures will be utilized on site to prevent erosion along streams (e.g., from road cuts or other grading).	X	x	x	x	x				
110	If debris blockages threaten bank stability and may increase sedimentation of downstream reaches, debris will be removed.	X	x	x	x	x				
111	If bank failure occurs due to debris blockages, bank repairs will use compacted soil and reseeding with native/sterile non-native plants.	X	x	x	x	x	x	x	x	x

112	Pumps and generators shall be maintained and operated in a manner that minimizes impacts on water quality and aquatic species.	X	x	x	x	x				

Source: ICF 2012

Notes:

These measures are paraphrased from Table 6-2 of the VHP (as revised via a minor modification dated March 17, 2016, which removed redundant measures) and are required for VHP Conditions 3, 4, and 5. This table indicates which specific AMMs pertain to each identified biological resources impact attributed to implementation of the Project.

A blank cell indicates that the measure is not applicable to that specific biological resources impact. VHP AMMs that are not applicable to any impact mechanism attributed to implementation of the Project are not included in this table.

3.4.3.1 Seismic Retrofit Project Construction

Seismic Retrofit construction activities that are relevant to fish resources involve mobilization (staging and stockpiling), maintaining reservoir elevations below FERC-restricted levels, further dewatering of the reservoir at the beginning of each construction season, temporary localized dewatering of Coyote Creek for pile driving in channel for one temporary bridge and the temporary dike structures, excavating and filling areas where dam facilities will be constructed, constructing temporary buildings and roads, installing temporary dikes, using temporary water treatment system, installing temporary diversions, using new intake structures, and retrofitting the dam, as well as demolishing the staging and stockpiling areas, temporary roads, bridges, dikes, and buildings, and restoring the Project Area to pre-Project or ecologically improved conditions, as feasible. Seismic Retrofit construction activities would also include blasting, grading, excavation and fill.

During implementation of Seismic Retrofit construction, there would be two categories of impacts on fisheries resources: (1) construction activities impacts (e.g., localized dewatering, earthwork, and facility construction) and (2) changes in instream flows downstream of the Seismic Retrofit Project Area as a result of continued maintenance of the reservoir at relatively low surface water elevation and further drawdown of the reservoir prior to and during the dry construction season (see the Project Construction Period Reservoir Operations and Drawdown Plan).

The impacts on fisheries resources from Seismic Retrofit construction activities in Coyote Creek and Anderson Reservoir were assessed qualitatively using the existing conditions baseline (as modified by FOCP implementation). Instream flows that would occur downstream of the dam and their water quality during Seismic Retrofit construction was assessed qualitatively and quantitatively using the Pre-FERC Order Baseline to account for continued maintenance of water surface elevations at a restricted level that was also carried through FOCP, as well as the Existing Conditions baseline. Significance conclusions for impacts related to construction phase hydrology are based on comparison to the Pre-FERC Order Baseline conditions to assure a full and accurate evaluation of all potential hydrology effects on fisheries relate to the extension of drawdown conditions starting with FOCP drawdown and extending through Project implementation. Unlike impacts related to construction of Project improvements and facilities, which can be accurately evaluated using an existing conditions baseline as modified by FOCP implementation, the fisheries effects of FOCP and Project drawdown are more accurately evaluated by comparison of Project construction phase operations to the Pre-FERC Order Baseline.

Qualitative impact analysis focused on Project Area construction activities in or near the channel, in and near the reservoir, and any resultant impacts on fisheries resources. Impacts would derive from localized dewatering, in-channel earth work, changes in water quality, reliance on imported water to maintain flows during construction, and incidental introduction, propagation, or movement of non-native species and pathogens. Construction activities and their timing were compared with temporal spatial expectations for the life history of each species assessed. When individuals of a special-status species were expected to be present and there was overlap in timing with a construction activity or change in water quality, impacts were identified and described and then considered with the application of components of the Project Description that avoid and minimize fish resources impacts, BMPs, and AMMs.

Seasonal timing and fish rescue and relocation are the major impact avoidance and minimization Project components for fish resources during construction activities for both the seismic retrofit and Conservation Measures construction. Throughout the construction analysis, the term “dry season work window” is used to convey the work window for dewatering and construction that is defined in the Project Description and may potentially be refined in minor ways or further restricted through permitting processes. Ultimately, timing most construction activities, particularly in-channel work in the dry season avoids and minimizes many impacts but not all to migrating anadromous fish in the study area and each species life-history timing is compared to the dry season work window to interpret impacts.

There are two types of fish rescue outlined in the Project Description with their differences explained here to avoid confusion throughout the impact analysis. One occurs based on monitoring data in coordination with the appropriate resource agencies and involves relocating steelhead and Pacific lamprey if water quality deteriorates and therefore is more relevant to the instream flows analysis with respect to water quality downstream of the dam during Seismic Retrofit construction. This type of fish rescue occurs under the Fish Rescue and Relocation Plan as defined in the Project Description.

A second type of fish rescue occurs when construction activities require localized dewatering in a specific location prior to doing in channel work. For Seismic Retrofit Construction this would occur for driving piles or casting piles in place for temporary bridge supports or installing temporary dike structures for the outlet and ATS, LLOW Construction, Cochrane Road realignment, and post-construction demolition. Localized dewatering would also occur for the ~~North Channel Extension,~~ Ogier Ponds~~,~~ and Phase 2 Coyote Percolation Dam Conservation Measures, and may occur for Maintenance of the North Channel Reach and is discussed in those respective Conservation Measure sections. In general, fish rescue during localized dewatering is covered under a Project component call a dewatering and aquatic species rescue and recovery plan that will be prepared as appropriate for each localized dewatering event by the respective contractor(s) and would require approval from the appropriate resource agencies and would cover all special status fish that could occur in the defined area of dewatering during the defined time of year required for that component. This may be one plan, or, more likely, multiple plans that cover different localized dewatering events for different construction components.

The quantitative part of the instream flows analysis used flow, temperature, and DO data from during the FOCP project in limiting months (dry construction season) to infer what flows might be during these months under Project and compare that to the Pre-FERC Order Baseline hydrology and water quality data. Additionally, quantitative analysis for water quality also used modeled sediment transport during construction to predict impacts on special status fish. Detailed methods are provided in Appendix F in the *Suspended Sediment Analysis* section. Generally, a USEPA Environmental Fluid Dynamics Code model was used to simulate erosion, deposition, and transport of sediment in Anderson Reservoir. Prediction of flow and sediment concentrations leaving the reservoir were used as input into the Coyote Creek HEC-RAS sediment model. URS (2020a, 2020b, and 2021) developed the combined sediment transport model and ran simulations with documented assumptions (in Appendix F) that provided predicted concentrations and durations of suspended sediment downstream of Anderson Reservoir under different phases and seasons of construction and at varying distances from the dam downstream to the estuary. Preliminary FOCP monitoring of suspended sediment concentrations suggests that the URS models slightly overestimate suspended sediment concentrations and therefore adverse suspended sediment impacts described for fish may be overestimated (Stillwater Sciences 2024).

The suspended sediment predictions were used to calculate the expected exposure of special-status fish to changes in suspended sediment concentration and duration with modeled constant flow and precipitation events. Using the modeled exposure concentration and durations, impacts on fisheries resources were predicted using the severity of ill effects (SEV) scale from Newcombe and Jensen (1996) to predict the likely impacts and their severity on each special-status fish species, as well as how that may impact the population on a larger scale. The calculations of the SEV values and how they apply to impact interpretation are explained in more detail in Appendix F, but the SEV scale goes from 0 to 14, where 0 is "nil effect" or no behavioral effect and 14 is greater than 80-100 percent mortality, with a spectrum of predicted impacts in between (SEVs 1-13) (see Table 2 in Appendix F).

For steelhead, an additional instream flow assessment was available that was prepared for Federal Endangered Species Act Section 7 consultation that provides quantitative modeling of steelhead habitat in the FCWMZ, the primary spawning and rearing reach, at flows ranging from 11-60 cfs (Stillwater Sciences 2021). These model results were used in the hydrology analysis to examine available habitat for rearing steelhead in the FCWMZ, particularly during the low flow, dry construction season work window when downstream flows would be partially or entirely made up of chilled imported water released from the CDL. This study allowed for the amount of available habitat to be determined at flows that will occur during the dry season construction period to better understand any potential impacts to steelhead.

This study used habitat criteria mapping (HCM) for fry rearing and juvenile rearing habitat. The HCM delineated a sampling framework consisting of a hierarchical channel network divided up into reaches within the FCWMZ and habitat units. Study reaches were defined based on broad-scale geomorphic channel characteristics. Habitat units (e.g., pool, riffle, run) were used to define individual sampling sites.

Information from aerial imagery, FAHCE POI reaches, channel type designations (Entrix 2000), and GIS spatial data for Coyote Creek was used to assess reach characteristics including channel gradient, channel confinement, bedform morphology, and drainage area and/or contributing flow. Three distinct study reaches were identified between Anderson Dam and Ogier Ponds. The frequency and distribution of habitat units in Coyote Creek were based on the October 2019 habitat inventory (AECOM 2021 ~~2020, unpubl. data~~), which delineated habitat based on CDFW Level III habitat types following Flosi et al. (2010). Sites that could be efficiently and effectively sampled were selected using a stratified sampling approach based on the following criteria:

- Suitable access to site and safe sampling conditions
- Suitable site conditions for high-resolution photography:
  - Because some sections of Coyote Creek have relatively dense vegetation and canopy that can obstruct imagery of stream channel features, these conditions were considered in site selection.
  - Site selection was reviewed after imagery was acquired and image quality was considered in final site selection.
- Suitable site conditions for efficient and effective data collection:

    - Sites with moderate length (not too long to limit time required for sampling), and not too short (pool [~5–40 m], riffle [~5–40 m], flatwater [~10–80 m]) were prioritized.
    - Cascade habitats were not sampled because they typically provide relatively little habitat and may be difficult to sample effectively.
    - Preference for sequences of two or more contiguous habitat units

- Spatial distribution of sites within each reach
- Representation of habitat types with greatest frequency by length
- Target sampling frequency greater than 10 percent of the reach by length

Estimation of habitat availability over a range of conditions requires habitat mapping to occur over a range of flows. Mapping flows were selected to represent a range of flow releases that may be under consideration for management (e.g., summer baseflow, winter baseflow, summer low flow). The four flow releases targeted for mapping and the actual flows during mapping surveys are shown in **Table 3.4-9**.

Table 3.4-9. Habitat Criteria Mapping Dates, Flows, and Rationale

Survey Dates	Targeted Flow Release (cfs)	Average Streamflow During Mapping Surveys (cfs)[a]	Rationale
May 14 and 15, 2020	60	60	Approximate upper end of flow release required for full groundwater recharge and additional surface flow
June 23 and 24, 2020	40	41	Approximate flow release required for full groundwater recharge
August 17 and 18, 2020	26	27	Approximate flow release required for minimal groundwater recharge (still groundwater depleting) when not a low-storage year
August 19 and 20, 2020	10	11	Approximate lowest winter baseflow and approximate minimum summer flow release

Notes: cfs = cubic feet per second

[a] Flows based on values reported in Coyote Creek at the Madrone stream gage location (Gage ID 5082).

HCM relies on binary habitat criteria to represent suitable habitat conditions for the target species and life stages of interest. Since HCM mapping criteria are binary, they are typically selected to represent “suitable” habitat, and not the full range of habitats that could be used. In application, field mapping was performed separately for the fry rearing and juvenile rearing life stages by delineating polygons that collectively met all the mapping criteria specific to each life stage (**Table 3.4-10**).

Table 3.4-10. Mapping Criteria for Estimating Steelhead Habitat Availability in Coyote Creek

~~1~~	Depth (ft)	Velocity (ft/s)	Proximity to Cover (ft)[1]	Minimum Polygon Area (ft^2)
Fry rearing [2]	0.1–1.2	<0.9	<2.4	6
Juvenile rearing [2, 3]	0.4–5.0	0.1–2.5	<4.8	6

Notes:

[1] CDFW (2014) defines cover as crevices among cobbles and boulders, ledges, aquatic vegetation, submerged overhanging branches of riparian vegetation, submerged organic debris, bent-over emergent sedges, low-hanging branches of riparian vegetation, high-flow debris clinging to overhanging riparian vegetation, and riverbank features.

[2] BasedI HSI ≥0.5 (CDFW 2014).

[3] Criteria for juvenile steelhead 2.4-5.9 inches (CDFW 2014). Maximum depth for juvenile rearing based on USFWS (2011).

Field mapping was performed on high-resolution orthorectified photographic base maps of the selected sites or series of contiguous sites. Imagery was collected utilizing an Unmanned Aircraft System along selected reaches of Coyote Creek downstream of Anderson Dam. A two-person crew mapped suitable habitat for focal life stages at each sampling site based on the mapping criteria described above. Mapping variance was assessed by conducting replicate surveys by different field crews within a subset of sample sites including one flatwater, one pool, and one run habitat. HCM was conducted separately by two different field crews for each of the three sample sites during each of the four flows assessed. Field mapping datasets were digitized in GIS and the areas mapped by each crew were compared. Suitable habitat area was calculated in GIS for each polygon delineated in the field based on the habitat criteria. Confidence intervals were calculated based on the combined variance in the measured habitat area per unit length by habitat type.

3.4.3.2 Conservation Measures Construction

Non-flow related Conservation Measures that are proposed for construction as part of the Project and analyzed are the Ogier Ponds Conservation Measure (Ogier Ponds CM), Maintenance of the North Channel Reach ~~North Channel Extension,~~ Maintenance of Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach, the Sediment Augmentation Program for the CWMZ ~~Ogier Ponds and Live Oak Reach~~, and Phase 2 Coyote Percolation Dam Fish Passage Enhancements (Phase 2 Coyote Percolation Dam CM). Impacts associated with construction and implementation of these Construction Measures require earth-moving construction in or near the channel downstream of Anderson Dam. Construction activities were assessed qualitatively compared with the existing conditions baseline (as modified by FOCP implementation). The qualitative analysis focuses on activities affecting the in-water environment: dewatering, diversion of water around a Project site, in-channel grading and grubbing, placement of gravel piles, and revegetation. Construction activities and their timing were compared with temporal and spatial expectations for the life history of each species assessed and, where there was overlap and the species was expected to be present at the time of the construction activity, impacts were identified, described, and considered with application of dewatering and aquatic species rescue and relocation plans (see Section 3.4.3.1 Seismic Retrofit Project Construction for more details and explanation), BMPs and AMMs.

3.4.3.3 Construction Monitoring

Construction Monitoring activities relevant to fisheries resources are:

- Construction Phase Water Quality Monitoring
  - General Water Quality Monitoring
  - Sediment Deposition Monitoring
  - Suspended Sediment Monitoring
  - Groundwater Monitoring
- Construction Phase Vegetation Monitoring
  - Construction Phase Wetland and Riparian Habitat Dryback Monitoring
  - Construction Phase *Phytophthora* Pathogen Management and Monitoring
- Construction Phase Fisheries Monitoring
  - Juvenile Rearing and Growth Comparative Studies
  - Environmental DNS Monitoring
  - VAKI Riverwatcher Adult Escapement Monitoring
  - ~~Construction Phase~~ Fish Rescue and Relocation Pla
  - Migration Flow Monitoring
  - Migration Study (PIT)
  - Spawning Surveys
  - Spawning Habitat Quality and Pool Depth Monitoring
  - Habitat Restoration Monitoring ~~n; Juvenile Rearing, Migration, and Growth Monitoring~~
- ~~Construction Phase Suspended Sediment Monitoring~~
- ~~Construction Phase Sediment Deposition Monitoring~~
- ~~Construction Phase Invasive Species Monitoring and Control~~
- ~~Construction Phase Wetland and Riparian Habitat Dryback Monitoring~~
- Construction Phase Reptile Monitoring
  - Northwestern ~~Western~~ Pond Turtle Monitoring
- Construction Phase Invasive Species Monitoring and Control
- ~~Coyote Creek Groundwater Monitoring~~
- ~~Construction Phase *Phytophthora* Pathogen Management and Monitoring~~

The impact analysis considers which of the monitoring activities actually occurs in or near the stream channel, and whether there would be any pathway for impacts to occur to special-status fish. For those activities that occur in or near the stream channel, they were assessed with regard to temporal spatial overlap with the life-history timing and occurrence of special-status fish or, with regard to fisheries monitoring, there may be direct impacts targeting fish (capture, handling, tagging) with the goal to improve information about how to best protect special-status fish, primarily steelhead. These impacts were then assessed for severity and population scale effects, as appropriate relative to the Existing Conditions, baseline as modified by FOCP.

3.4.3.4 Post-Construction Seismic Retrofit Operations (FAHCE Rule Curves and Instream Flows)

The FAHCE rule curves are intended to provide spawning and rearing habitat for steelhead and Chinook salmon, passage for adult steelhead and Chinook salmon to reach suitable spawning and rearing habitat, and adequate passage for the out-migration of juveniles. The FAHCE rule curves provide winter base flows, pulse flows to aid migration, and summer base flows to support each life stage, and provide a framework for ramping flows and reservoir operations under low-flow conditions. Winter base flows would be adequate to provide 5 cfs base flow at the Madrone stream gage November 1–April 30. If the combined storage in Anderson and Coyote reservoirs exceeds 80,000 acre-feet, and it is safe to do so, spring pulse flows of 50 cfs for a period of 5 consecutive days would be released from Anderson Reservoir twice during the period of February 1–April 30, with flood releases and spill events in excess of 50 cfs for 5 consecutive days during this period considered a pulse flow event. Summer base flows would target maintaining 64.4 °F (18 °C) in as much of the CWMZ as possible from May 1–October 31. Flows would be ramped up and down to allow aquatic animals to acclimate to changing flows.

Valley Water would release imported water to the downstream end of the CWMZ, via the ~~CVP~~ Cross Valley Pipeline Extension, when supplies are available, and releases are necessary for managed aquifer recharge and/or to meet minimum flow requirements. These releases would occur if stream flow from Anderson Dam does not reach the Cross Valley Pipeline Extension outfall and areas of dryback are present downstream. Since the creek would be dry in proximity of the Cross Valley Pipeline Extension, no temperature restrictions would apply to these releases. Such releases would provide flows in lower reaches of Coyote Creek to prevent further dryback, as well as replenish groundwater storage that is important for maintaining aquatic, wetland, and riparian habitats along the creek and in North Coyote Valley, while not influencing conditions in the CWMZ that is wetted from Anderson Dam releases. ~~WEAP modeling flows and water temperature~~

WEAP modeling flows and water temperature

Valley Water's FAHCE WEAP model uses known hydrology from the historical record (January 1, 1991, to December 31, 2010) and measured habitat variables and applies different scenarios to see how salmonid habitat changes with different instream flow operations. The general methods are summarized here with a more detailed technical methods discussion in Appendix F ~~G~~. The WEAP model was used to provide a quantitative basis from which to assess impacts of post-construction implementation of the FAHCE reservoir re-operation rule curves (i.e., post-construction Seismic Retrofit instream flow operations) on fisheries resources compared with the Pre-FERC Order Baseline Conditions and Future Baseline conditions. The way that FAHCE flows would interact with additional habitat created under the Ogier Ponds CM , the Maintenance Activities at the Live Oak Restoration Reach, and the Sediment Augmentation Program for the CWMZ, in combination with the changes in conveyance and passage under the North Channel Extension (completed during FOCP), Ogier Ponds CM~~,~~ and Phase 2 Coyote Percolation design was also incorporated into the analysis to provide a comprehensive understanding of how the FAHCE flows would benefit or impact fish resources.

The WEAP model was developed specifically for steelhead and Chinook salmon. The WEAP model predicts incubation adjusted spawning habitat (spawning habitat that incorporates time and conditions for successful egg incubation), fry rearing habitat, juvenile rearing habitat, adult migration conditions, and smolt migration conditions based on available and suitable substrate, water temperature, depth, velocity, and other variables as appropriate (Appendix F). Appendix F provides detail on how each of these habitat statistics are defined for steelhead and Chinook salmon, and how the model applies prior field surveys to habitat availability predictions and model calibration.

Pacific lamprey, Sacramento hitch, and Southern coastal roach were not the focus of the WEAP model, but it was possible to use a semi-quantitative approach with some qualitative interpretation. However, the WEAP model can be used to assess habitat availability when habitat needs overlap steelhead or, when that is not possible, changes in flows, temperature, wetted area, and thalweg depth were used to infer relative changes in habitat for each relevant life-history stage (incubation-adjusted spawning, fry rearing, juvenile rearing, and conditions for smolt and adult migration) (Appendix F). Relevant scientific studies were then applied qualitatively to interpret how these relative changes may benefit or impact these three species compared with baseline conditions.

The impacts of post-construction operations on the intertidal species (longfin smelt, white sturgeon, and green sturgeon) were based on qualitative assessment of the intertidal areas, how much freshwater flow would change under the FAHCE rule curves, and the seasonal presence of these species when available.

Riffle sculpin do not occur downstream of Anderson Dam and are found in Upper Penitencia Creek; therefore, there would be no impact on this species from post-construction operations so there is no method described for assessment.

3.4.3.5 Seismic Retrofit and Conservation Measures Post-Construction Operations and Maintenance

Post-construction operations, maintenance, and monitoring activities for the Project are:

- Seismic Retrofit (Anderson Dam) and instream flow operations to implement FAHCE rule curve flows for the benefit of steelhead and Chinook salmon
- Anderson Dam (Seismic Retrofit) maintenance
- Ogier Ponds operations and maintenance
- North Channel Reach operations and maintenance
- Sediment Augmentation Program operations
- Live Oak Restoration Reach maintenance
- Maintenance and Operation of Phase 2 Coyote Percolation Dam Fish Passage Enhancements
- ~~Maintenance of gravel augmentation in the Live Oak Restoration Reach, Ogier Ponds restored and reclaimed channel, and the related Sediment Augmentation Program to address geomorphic processes within the CWMZ~~

- ~~North Channel Extension, Ogier Ponds and Phase 2 Coyote Percolation Dam~~
- ~~North Channel Extension, Ogier Ponds (including channel, wetlands and pond habitat), and Phase 2 Coyote Percolation Dam maintenance~~

Anderson Dam Post-Construction Operation and Maintenance

Post-Construction Seismic Retrofit (Anderson Dam) and Instream Flow Operations

Following construction, Anderson Dam would be operated with the new multi-level intake and higher conveyance capacity, and in accordance with the FAHCE rule curves. This is considered for each species in the impact analysis in how water can be drawn from the reservoir at multiple levels enhancing temperature control downstream and water can be conveyed at a much greater rate for emergency drawdowns, which incidentally provide higher flows downstream than under the Pre-FERC Order Baseline. The impact analysis qualitatively considers these changes and applies relevant science to interpret any impacts or benefits from the post-construction dam operations.

Post-Construction Seismic Retrofit (Anderson Dam) Maintenance

Valley Water would maintain the newly retrofitted Anderson Dam and Reservoir per Valley Water's existing DMP and PMP. Maintenance of Anderson Dam facilities was previously evaluated in the Final DMP Program EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). The DMP and the PMP includes BMPs and mitigation measures like gravel augmentation and large wood placement to reduce biological resources impacts. For most biological resources impacts, impacts of the Project's post-construction maintenance activities would not differ substantially from those impacts identified in the DMP EIR. Furthermore, previously identified DMP impacts would not be exacerbated with implementation of the Project.

Conservation Measures Operations and Maintenance

Operations and Maintenance of Ogier Ponds CM

The restored channel created via the Ogier Ponds CM will operate and function as a natural creek channel. There will be no management of flows or manipulation of features as a result of the new creek channel operations. High flow weirs leading to the ponds will be activated infrequently when flow levels reach 2000 cfs, and will be spillover, not requiring any operational actions.

For the Ogier Ponds CM, maintenance would include vegetation management, vegetation restoration, and inspection and repair of the berms, weirs, habitat enhancement, and erosion protection. These maintenance activities were analyzed using the same methods as Conservation Measure Construction. Maintenance of the Ogier Ponds CM will be covered under the SMP and SMP EIR.

~~*Operations and Maintenance of Anderson Dam Outlet*~~ *Operations and Maintenance of the North Channel Reach* ~~*Extension*~~

~~The distribution of flow between the south and north channels will be achieved by construction of a weir on each channel. The intent is to maintain the south channel as the primary flow path at low flows while reducing the potential for erosion in the south channel during higher flows. The north channel will become wetted at flow ranges above the normal operations under the FAHCE rule curves; flow will overtop the north weir at flows above 228 cfs. Releases in this range occur when storage levels within Anderson Reservoir are high and Valley Water needs to maintain storage capacity in the reservoir. Releases above 228 cfs will be infrequent and the release rates during these events will be variable and based on the level of storage, anticipated rain events, downstream flow conditions, and other factors. As high flow releases return to the normal FAHCE range of operations, reservoir releases will ramp down according to rules established in the FAHCE *Settlement Agreement*.~~

Long-term maintenance of ~~Maintenance for~~ the North Channel Reach ~~Extension~~ would include removal of debris or vegetation from the channel, and possibly dewatering and grading of the channel, if necessary, so that the channel maintains positive drainage (to avoid fish stranding). These maintenance activities ~~were analyzed using the same methods as Conservation Measure Construction Maintenance of the Anderson Dam Outlet North Channel Extension~~ will be covered under the SMP and SMP EIR.

Maintenance of ~~Sediment Augmentation Program and~~ Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach

The impacts of maintaining the ~~both Ogier CM and~~ Live Oak Restoration Project~~, and the Sediment Augmentation Program (associated with Live Oak Restoration Project and Ogier Pond CM maintenance) were~~ was analyzed using the same methods as Conservation Measure Construction. ~~Implementation of the Sediment Augmentation Program, maintenance~~ Maintenance of the Live Oak Restoration Reach~~, and maintenance of the new creek channel created as a part of the Ogier Ponds CM~~ will be consistent with SMP and its EIR.

Operations of the Sediment Augmentation Program

The impacts of operating the Sediment Augmentation Program were analyzed using the same methods as Conservation Measure Construction. Implementation of the Sediment Augmentation Program will be consistent with SMP and its EIR.

Maintenance and Operation of Phase 2 Coyote Percolation Dam Fish Passage Enhancements

Maintenance for the Phase 2 Coyote Percolation Dam CM would include periodic removal of sediment, vegetation management, repair of rock slope protection, and replacement of any in-channel bio-engineered habitat enhancements, as needed. These operations and maintenance activities were analyzed using the same methods as Conservation Measure Construction. Maintenance of the Phase 2 Coyote Percolation Dam CM will be covered under the ~~SMP and~~ DMP and will undergo CEQA review under that program.

Consistent with current operational rules of the Coyote Percolation bladder dam, installed as a part of FOCP to allow more flexible operations for the benefit of steelhead than are possible with a flashboard dam ~~Dam~~, the bladder dam would be lowered only during high flow events (exceeding approximately 250 ~~320~~ cfs) and then be raised after high flow events have receded. The facility would pass flows up to 250 ~~320~~ cfs via a combination of the fish ladder and a new overshot weir which is replacing one of the existing radial gates. When flows are predicted to exceed 250 ~~320~~ cfs, releases would be made from the percolation pond via an overshot weir to reduce storage and then deflate the dam when safe to do so.

Post-Construction Project and FAHCE Adaptive Management

The Project and FAHCE AMP would guide post-construction adaptive management of flow and non-flow Conservation Measures. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting:

Measurable Objectives. The FAHCE *Settlement Agreement* (2003) and the FHRP provide measurable objectives for steelhead and salmon fisheries and their habitats. These objectives would be achieved through implementation of FAHCE flow and non-flow measures for Coyote Creek, along with implementation of additional conservation measures identified in this Project description (see Appendix D).

Monitoring. Monitoring activities would focus on compliance, validation, effectiveness, and long-term trends. Systematic monitoring would be conducted of actual habitat conditions affected by the post-construction operations flow measures and non-flow conservation measures implemented under the FAHCE, FOCP, and Project to determine whether the conservation measures are contributing to the achievement of measurable objectives. Monitoring activities would evaluate the performance of the entire program in improving habitat quality and availability for steelhead and salmon, as well as the performance in each phase of the program in reducing or eliminating limiting factors affecting various life stages of steelhead and salmon, where such conditions are directly attributable to Valley Water facilities and operations in Coyote Creek.

Adaptive Actions. The Project and FAHCE AMT, including NMFS, other regulatory agencies, and non-governmental organizations (NGOs), would review potential adaptive actions and prioritize these actions for implementation. This may include modification of post-construction operations flow measures and non-flow conservation measures identified under FAHCE and in this EIR, as well as individual regulatory agency requirements, as appropriate, to help achieve measurable objectives.

Reporting. The AMT would synthesize and analyze results, evaluate progress attained by flow and non-flow measures, and identify potential adaptive actions where needed.

Appendix D summarizes the adaptive management goals, measurable objectives, monitoring types, methods and frequency, triggers for potential management actions, and potential management actions to be considered for implementation by Valley Water in coordination with the regulatory agencies of the FAHCE AMT (Project AMT).

The monitoring program to inform selection of adaptive management measures to implement in response to management triggers has been organized into four ~~three~~ categories, as follows:

- Compliance monitoring includes administrative metrics such as reservoir releases and cold-water pool volume, compliance with the schedule for implementing a particular program element (such as a site-specific passage impediment remediation project), or progress on planning or feasibility studies.
- Validation monitoring includes physical monitoring of instream flows, depth, velocity, water temperatures within the CWMZ and FCWMZ, areas of enhanced habitat, jump height and pool depth for passage impediments, habitat mapping to assess suitability for various life stages of salmonids, validating flow-habitat relationships, and other elements of the program.
- Effectiveness monitoring evaluates the progress made towards the overall restoration objective established for the FAHCE Program by the FAHCE Settlement Agreement.
- Long-term trend monitoring includes evaluation of ecosystem responses to management actions and/or natural drivers, including monitoring adult salmonid abundance, juvenile steelhead density, salmonid migration, steelhead genetics, ~~,~~water quality, and overall species composition.

The Project and FAHCE AMT would play an important role in adaptive management decision making, as described in detail in the FAHCE AMP. Considerations for adaptive management decision making include inter-annual and seasonal variation in hydrologic conditions, other constraints and limiting factors affecting achievement of the overall management objectives, monitoring results of the actual habitat enhancement measures already implemented, opportunities for improving habitat for other fish, wildlife, and plant species, and more generally, the ecological conditions of the watersheds. Data and analysis from compliance, validation, effectiveness, and long-term trend monitoring, evaluated using measurable objectives, would help determine whether refinements need to be made to post-construction operations reservoir releases, fish passage projects or habitat restoration projects carried out as part of the FOCP and Project to incrementally improve instream fisheries habitat conditions.

While the Project and FAHCE AMP would be implemented pursuant to the adaptive management framework established by the FAHCE Program, the Project and FACHE AMP also supplements the FAHCE AMP, which would continue to provide for study, evaluation and selection of future Coyote Creek FAHCE Phase 2 measures, if required, as outlined in the FAHCE Settlement Agreement (2003) and FHRP. The FAHCE Settlement Agreement contained a menu of potential Phase 2 measures that have not been defined or evaluated for feasibility. Once Phase 1 measures are fully implemented and 10-year monitoring results are analyzed, a determination of whether or not Phase 2 measures (e.g., revised water releases from Anderson to provide for continuous stream flows to approximately Metcalf Road, remediate Priority No. 2 barriers, implement a trap and truck operation to relocate adult steelhead into upper watershed habitat, etc.) are necessary will be discussed through the FAHCE AMP decision making process.

The AMP consists primarily of monitoring and determination of what incremental modifications of Project reservoir releases and Conservation Measures, including those that are also FAHCE Phase 1 measures, need to be made to optimize their effectiveness for fisheries resources.~~;~~ Therefore, over the long-term these activities would benefit fisheries resources.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Valley Water would also collaborate with the NOAA Fisheries Southwest Fisheries Science Center regarding sampling methodologies to ensure that fisheries population status and trends can be established over time. Impacts of these monitoring activities are evaluated in the impact analyses below. They would be minor and similar to the impacts of ~~Consruction~~ Construction Monitoring. Small numbers of people conducting the monitoring will be visiting a number of areas throughout the Seismic Retrofit and Conservation Measures Project Areas. Those people, their vehicles, and equipment may result in minor, localized, and temporary disturbance of aquatic, wetland, and riparian habitats, vegetation, and special-status fish.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. These impacts are considered here at a programmatic level because the detailed characteristics, timing, and/or locations of the proposed adaptive measures are not known at the time of EIR preparation. Project-specific CEQA review would be undertaken in the future, as necessary, when specific projects are proposed and project-specific details are available. Impacts of these adaptive actions are evaluated in the impact analyses below.

Impacts of Project and FAHCE AMP monitoring and adaptive actions are included below in the Post Construction Operations, Maintenance, and Monitoring sections below.

3.4.3.6 Thresholds of Significance

In the following analysis, an adverse impact is referred to as an "impact", and beneficial impacts are referred to as "benefits" or the Project "benefitting" the species. The term "no impact" does not imply that there is no benefit; only that there is no adverse impact considered in the context of the thresholds of significance from the Project components on the fish species. For the purposes of this EIR, and consistent with *CEQA Guidelines* Appendix G, the Project would result in a significant impact to fisheries resources if it would:

> **FR-1**: Have a substantial adverse effect, either directly, through habitat modifications, or through substantial interference with movement of any fish species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW, NMFS, or USFWS, in the fisheries resources study area.

Fish species is interpreted to mean the species' population in the Coyote Creek Watershed meaning that a substantial adverse effect to the population is considered a significant impact.

Issues Dismissed from Further Review

Appendix G of the *CEQA Guidelines* states that a project may have a significant environmental effect if it would interfere substantially with the movement of any native resident or migratory fish species. For migratory (anadromous) fish species that move substantial distances, this impact is evaluated in Impact FR-1. For native resident fish species, this EIR does not evaluate movement impacts because these species are not migratory, and the Project does not introduce any new passage barriers in the study area.

Appendix G of the *CEQA Guidelines* also states that a project should be assessed for a conflict with the provisions of an adopted HCP, NCCP, or other approved local, regional, or state HCP. The only HCP, NCCP, or other approved local, regional, or state HCP relevant to the study area is the VHP. Several plant and animal species are covered by the VHP; however, no specific fish species are included in the VHP. Therefore, impacts on fish species covered in this impact assessment would not conflict with an adopted HCP, NCCP, or other approved HCP with respect to fisheries resources. The potential conflict with the provisions of an adopted HCP, NCCP, or other approved local, regional, or state HCP as it applies to terrestrial and other non-fish aquatic resources is analyzed in Section 3.5, *Biological Resources – Wildlife and Terrestrial Resources*.

Also, payment of VHP Fees is excluded from the analysis because payment of the fees would not have any adverse impacts, but rather may result in result in the SCVHA using the fees to acquire, preserve, manage, and restore sensitive habitats that are impacted by the Project.

Chinook salmon EFH is included in the analysis for Chinook salmon (FR-2). Coho EFH would have the same impacts as Chinook salmon EFH but coho salmon are not present in the study area, so impacts on EFH were not assessed further. Coastal pelagic and groundfish EFH would have similar impacts as those on the estuarine species' habitat analyzed in this document (i.e., increased sediment transport and an extremely small change in salinity in the intertidal zone) but the impacts would be even less because the only potential impacts would be increased sediment transport to the bay, which would have no impact on coastal pelagic and groundfish EFH and may actually benefit this habitat; therefore, there is no further analysis of coastal pelagic and groundfish EFH.

Finally, the following construction monitoring components: Water Quality Monitoring, Suspended Sediment Monitoring, Wetland and Riparian Dryback Monitoring, Phytophthora Pathogen Management and Monitoring, Western Pond Turtle Monitoring, and Milkweed Monitoring were eliminated from the fisheries resources impact analysis because either the methods used for monitoring do not affect fish habitat or the methods occur from the bank, and the monitor can conduct the monitoring without entering the water; therefore, there would be no impact to fisheries resources.

3.4.4 Impact Analysis

***Impact FR-1: Have a substantial adverse effect, either directly, through habitat modifications, or through substantial interference with movement on any species identified as a candidate, sensitive, or special-status fish species in local or regional plans, policies, or regulations, or by CDFW, NMFS, or USFWS in the fisheries resources study area* (Less than Significant)**

Impact FR-1a: Central California Coast Steelhead (Less than Significant)

Seismic Retrofit Construction

Seismic Retrofit Construction Activities

Seismic Retrofit construction activities could impact steelhead individuals or their habitat from immediately downstream of the dam to Alviso Slough. Seismic Retrofit construction activities upstream of the dam in the reservoir would not impact protected steelhead individuals directly, as they are not present in this area. However, there would be increased sediment transport compared with the existing conditions baseline when the reservoir is held at lower elevations. The lowered water elevations in the reservoir would result in sediment that would be normally inundated in the reservoir being exposed, and therefore becoming more erodible and mobilizing as water flows into and then out of the reservoir. While associated with construction activities, sediment transport is more applicable to the flow operations during construction that would carry sediment downstream; therefore, impacts from increased sediment transport are analyzed in the next section *Instream Flows during Seismic Retrofit Construction*, while this section analyzes the impacts of Seismic Retrofit construction activities (e.g., use of heavy equipment, pile driving, blasting, staging, and stockpiling, etc.).

Impacts on steelhead from Seismic Retrofit construction activities (pile driving, earth moving, construction of roads, etc.) <u>downstream of the dam</u> would be minimized through the in channel work window (June 15 to October 15) as defined in *Section 2.5.1.1 – Schedule*. BMP BI-2 will also protect steelhead by avoiding routine use of vehicles and equipment in Coyote Creek downstream of Anderson Dam between October15 and June 15.

Seasonal timing is important for steelhead life-history stages. The dry season work window limits in-channel construction activities <u>downstream of the dam</u> during adult upstream migration and spawning. Rearing juvenile steelhead could always be present downstream of the dam.[7] Construction activities occurring downstream of the dam could impact steelhead located in the immediate vicinity of the activity through noise or vibration. Noise and vibration disturbance could happen during use of heavy equipment in or near the stream channel, pile driving or casting piles in place in or near the stream channel for all bridges and dike structures constructed in Years 1 and 2, and during demolition of the temporary bridges and dike structures in Year 7. Pile driving for the in-reservoir cofferdam in Year 2 would be too far away to impact steelhead and is not considered further. To facilitate these in-channel construction

[7] It is rare but possible that adult steelhead could occur in the summer if they migrated into the system during the wet season and did not migrate out but also did not die post-spawning. Because BMPs apply generally to *O. mykiss*, these fish would also be protected if they were to occur.

activities and avoid impacts on steelhead, localized dewatering would take place and steelhead would be excluded from the work area. Implementation of BMPs and AMMs as well as the dewatering and aquatic species rescue and relocation plan for dewatering activities will minimize impacts that may occur during localized dewatering activities.

Localized dewatering has the potential to strand steelhead or trap them in pools, subjecting them to increased predation pressure and water quality degradation or they could be taken up into pumps used for dewatering surface water or bypassing water around the work area. Steelhead would be rescued and relocated during localized dewatering according to the relevant approved dewatering and aquatic species rescue and relocation plan. BMP BI-2 will also protect steelhead by avoiding routine use of vehicles and equipment in Coyote Creek downstream of Anderson Dam between October 15 and June 15. BMPs GEN-35 and WQ-3, as well as AMM-17, will also require any pumps that are used for either dewatering or diverting waters around the work area to be screened, in accordance with NMFS and CDFW criteria, to prevent the uptake of fish, and minimize the potential for fish to be injured and/or killed during the dewatering process. Therefore, impacts from localized dewatering would not be significant.

Rescue and relocation plan capture methods could include backpack electrofishing, seining, dip netting and/or capturing by hand. Impacts to fish may include stunning, netting, capturing, and handling, all of which may cause acute physiological stress that is temporary. All fish are expected to recover, but injury or mortality to fish can happen occasionally. Most steelhead tolerate short duration capture and handling well. Expected acute physiological stress during rescue and relocation would be a lesser impact than mortality due to stranding, predation, and/or deteriorating water quality conditions if rescue and relocation efforts during localized dewatering events were not implemented.

The Invasive Species Monitoring and Control Plan and AMM-91 may also reduce predation pressure and/or competition from nonnative fish, crayfish, American bullfrogs, and red-eared sliders in these areas, at least in the short-term (long term benefits are less likely unless eradication is achieved). BMP BI-11 and AMM-90 will further minimize impacts from predators by requiring that trash be removed daily from the construction area, limiting attraction to the site by predators.

Construction activities also have the potential to degrade water quality downstream of the work area due to increased suspended sediment or other materials in the water which could impact rearing steelhead located downstream of the dam. BMPs GEN-20 and WQ-16, as well as AMM-66, AMM-84, and AMM-97, will reduce sediment entering the channel from the work area during precipitation events by installing erosion control measures (e.g., silt fences, straw bales, etc.) and visually inspecting erosion control measures during and following extended storm events. BMPs GEN-26, GEN-31, GEN-30, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, AMM-11, and AMM-100 will minimize the pollution from vehicle fluids or other oily, greasy, or sediment-laden materials that could enter the creek from the work area by maintaining clean conditions at work sites, keeping spill kits available onsite to clean up any accidental spills, training personnel to properly use spill kits, fueling and cleaning vehicles and equipment offsite, utilizing secondary containment for any fluid changes onsite and storing contaminating materials, keeping vehicles maintained and clean, and inspecting vehicles and equipment daily for leaks prior to initiation of work. BMP WQ-15 will protect steelhead downstream of the work area from impacts of degraded water quality by keeping any oily, greasy, or sediment-laden substances away from places they may enter the waterway and monitoring water turbidity changes downstream of the work area and any discharge points.

Noise and vibration disturbance could occur during use of heavy equipment in or near the stream channel downstream of the dam, pile driving or casting piles in place in or near the stream channel for all bridges and dike structures constructed in Years 1 and 2, and during demolition of the temporary bridges and dike structures in Year 7. Pile driving/casting would occur in the dewatered northern channel which would be at least 200 feet from where steelhead could occur. Because steelhead would be over 200 feet from the pile driving/casting and the activity would not occur in the water, pile driving/casting is not likely to result in injury or mortality but could cause temporary acute physiological stress and could result in fish moving from the area or rearing steelhead temporarily switching from foraging to hiding under cover. Pile driving activities would be temporary, and fish would behaviorally regulate their exposure by swimming away or hiding. Upon completion of pile driving/casting, fish could return to previously abandoned areas or come out from hiding and would likely recover from the acute physiological stress and foraging disturbance. BMP BI-2 and the dry season work window will minimize impacts to migrating and spawning steelhead from noise and vibration injury from pile driving or casting in place for the North Channel Temporary Bridge. This work window minimizes impacts to migrating steelhead, because adults ~~outmigrate~~ immigrate December through April and smolts outmigrate February through May. BMP BI-2 would also protect steelhead by avoiding routine use of vehicles and equipment in Coyote Creek downstream of Anderson Dam between January 1 and June 15. Rearing juveniles occur in Coyote Creek year-round; however, steelhead are less likely to be close to the pile driving activities because, as described above, in-channel work would require localized dewatering and exclusion of steelhead from the work area, and it is likely that the North Channel would already be dry at that time. It is possible that steelhead excluded from the work area may still be subject to noise and vibration disturbance, though any noise and vibration disturbance would attenuate prior to reaching locations where steelhead are present, any impacts would be sublethal and short-term and therefore less than significant.

In Year 5, blasting at the BHBA could directly impact steelhead. Blasting would occur throughout Year 5 (11 months) and blasting noise and vibrations may cause acute physiological stress, changes in behavior (e.g., changing from foraging to hiding), and, in extreme cases, injury or death if the noise and vibrations are substantial, close by, and/or repeated. However, BHBA is located about a quarter mile away from the Coyote Creek channel on the other side of the dam; therefore, sound waves from blasting would attenuate prior to reaching in-channel areas where steelhead are present, potentially causing some acute physiological stress or temporary behavior changes, but injury and death would be unlikely. Blasting procedures would be developed by a qualified blaster to control noise, air-overpressure, ground vibration, flyrock, and dust. The contractor would be required to implement minimization measures to limit noise generated by blasting to 75 dBA or less towards residential receptors which would also minimize noise and vibration impacts on steelhead. Overall, impacts on steelhead from noise and vibration disturbance from blasting at the Basalt Hill Borrow Site would be less than significant.

A 1,300-foot-long temporary access road would be established on the downstream slope of the dam, connecting to an approximately 1,900-foot-long access road along the Anderson Dam Trail from the existing dam down into Staging Area 1 (Live Oak Picnic Area). Earthwork for establishing the road would be out of the channel in upland areas and require minor vegetation removal and grading. Noise or vibration from the earthwork may result in acute physiological stress with the same impacts as described above for pile driving and blasting. Grading and compaction of roads could allow more runoff to the channel during precipitation events than under the existing conditions baseline. This could introduce sediment and pollution from vehicle fluids to the creek and, if exposure was high enough and long enough, could result in behavior changes (moving downstream where pollution is more diluted), injury, illness, and, in extreme cases, mortality.

Implementation of BMPs GEN-20 and WQ -16, as well as AMM-66, AMM-84, and AMM-97 will reduce sediment entering the channel from the temporary access road during precipitation events by installing erosion control measures (e.g., silt fences, straw bales, etc.) and visually inspecting erosion control measures during and following extended storm events. BMPs GEN-26, GEN-31, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, and AMM-11 will minimize the pollution from vehicle fluids entering the creek from the temporary access road by keeping spill kits available onsite to clean up any accidental spills and training personnel to properly use spill kits, fueling and cleaning vehicles and equipment offsite, keeping vehicles maintained and clean, and inspecting vehicles and equipment daily for leaks prior to initiation of work. These BMPs will minimize impacts on the steelhead population from temporary access road construction so that they are less than significant.

Staging and stockpiling areas located immediately downstream of the dam could introduce sediment to the channel during precipitation events. Pollution could also be introduced from vehicles and equipment in these staging and stockpiling areas. If exposure to increased sediment and pollution was high enough and for a long enough duration, steelhead could exhibit behavior changes (moving downstream where pollution is more diluted), injury, illness, or mortality. BMPs GEN-21 and WQ-4, as well as AMM-66, AMM-67, AMM-68, AMM-84, and AMM-97 will reduce sediment entering the channel from staging and stockpiling areas downstream of the dam by covering sediment piles or surrounding areas with erosion control measures, filtering runoff, limiting the length of time materials can be stockpiled, and not placing sediment where it could spill into water bodies or storm drains. BMPs GEN-26, GEN-31, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, and AMM-11, will minimize the pollution entering the channel by maintaining clean conditions at staging and stockpiling areas downstream of the dam, keeping spill kits available onsite to clean up any accidental spills and training personnel to properly use spill kits, cleaning vehicles and equipment off-site, keeping vehicles maintained and clean, inspecting vehicles and equipment daily for leaks prior to initiation of work, and utilizing secondary containments when fueling vehicles and equipment in staging and stockpiling areas. These BMPs and AMMs will minimize impacts on the steelhead population from staging and stockpiling so that they are less than significant.

Once Seismic Retrofit construction is complete, temporary access roads would be removed and access road areas would be restored to pre-construction conditions as discussed in Section 2.5.6, *Site Restoration*. Demolition could result in temporary acute physiological stress and behavior changes from noise and vibration similar to those described above for pile driving, blasting, and access road construction. Downstream of the dam, BMP BI-2 and the in channel work window will protect most steelhead during migration and spawning from noise and vibration injury. This work window minimizes impacts to migrating steelhead because adults immigrate December through April and smolts outmigrate February through May. BMP BI-2 will also protect steelhead by avoiding routine use of vehicles and equipment and dewatering in Coyote Creek downstream of Anderson Dam between October 15 and June 15. However, rearing juveniles occur in Coyote Creek year-round. Impacts from road demolition would be temporary, sublethal, and less than significant to the steelhead population for the same reasons described for pile driving and access road construction.

Following demolition, disturbed areas would be restored to pre-construction conditions and seeding will occur to replace removed vegetation through BMP REVEG-1 downstream of the dam. Reestablishing native vegetation and riparian habitat downstream of the dam would benefit steelhead in the long term by shading the creek and providing habitat complexity. Additionally, the retrofitted dam would be allowed to refill once ~~seismic~~ restrictions are lifted allowing more storage for cold water pool management post-construction compared to the existing conditions baseline, which would benefit steelhead by allowing more consistent suitable rearing habitat throughout the dry season. Finally, the seismically retrofitted dam would have a new, multi-level intake structure that would allow more precise temperature control on downstream releases benefiting steelhead relative to the existing conditions baseline in the long term.

Overall, Seismic Retrofit construction activities may adversely impact steelhead, but the impacts will not be substantial with the application of BMPs, AMMs, the dry season work window, and the aquatic species rescue and relocation plans for any in-channel work that requires localized dewatering ; therefore, Seismic Retrofit construction impacts from the above-described construction activities would be less than significant on steelhead and their habitat in the short-term. The complete retrofitted dam would benefit steelhead in the long-term relative to existing conditions due to changes proposed in post-construction operations facilitated by completion of the retrofit and other Conservation Measures.

Instream Flows during Seismic Retrofit Construction

This section analyzes the impacts of instream flows downstream of Anderson Dam during Seismic Retrofit construction on steelhead compared with the Pre-FERC Order, Future, and existing conditions baseline when applicable. During Seismic Retrofit construction, there would be wet seasons, spring reservoir drawdown, and dry construction seasons (i.e., the work window when in-channel work could occur downstream of the dam). Reservoir water surface elevation would be restricted to deadpool. Any inundation behind the dam would be drawn down as fast as the outlet capacity would allow. During the wet season, all inflows to the reservoir would be diverted and released downstream as quickly as possible given the type of diversion (Stage 1 or Stage 2) to maintain an elevation at deadpool. In April, or when conditions allow following April, the reservoir would be drawn down to the Stage 1 or Stage 2 elevation at or below deadpool as needed to conduct construction activities during the work window. The rate of drawdown would depend on antecedent conditions in the watershed and the type of diversion in place (Stage 1 or Stage 2) but should take about 2-4 weeks. Once the reservoir has been drawn down to the correct elevation to initiate in-channel work, then the construction activity for that year would commence and any inflows coming into the reservoir would be diverted (or sometimes pumped) around the work area and released downstream. As described in Section 2.5.3.1 and 2.5.4.2, localized groundwater that is pumped from the dam footprint throughout construction would be pumped from the site and routed through an ATS. The ATS would remove sediment, reduce turbidity, and balance pH from these waters prior to release into Coyote Creek, downstream of the dam. Pumping would occur within the construction activity season (i.e., the dry season work window). Diverted water would not be treated.

Construction Phase Hydrology and Hydrology Conservation Measures

Project seismic retrofit construction will necessitate about seven more years (beyond FOCP) of maintaining the reservoir at the FERC-restricted elevation, during the wet season, and drawing it down to lower elevations to accommodate construction activities during the work window. In order to maintain the reservoir at the restricted elevation, inflows will be bypassed through the reservoir and released to Coyote Creek as quickly as possible, depending on the diversion in place at the time. Inflows into the reservoir bypassed to Coyote Creek will come from run off from unaltered tributaries of the reservoir (Las Animas and Packwood creeks) and releases from Coyote Reservoir, which will follow normal operations. Normal operation of Coyote Reservoir, an FOCP Conservation Measure, will continue during the Project construction period, such that dry-season flows released from Coyote Reservoir would continue as in the existing conditions and would be transferred through Anderson Reservoir, then released downstream of Anderson Dam through the stage 1 or stage 2 diversion system as applicable. Most losses between Coyote and Anderson Reservoirs are due to evaporation (at elev. 490 ft, 1 cfs loss due to evaporation relative to inflow during the dry season), with minimal infiltration. Losses are countered by natural springs that emerge into Coyote Creek where it enters Anderson Reservoir.

During Project construction, Valley Water would continue to implement the FOCP Conservation Measure of releasing 10 cfs of local water through the stage 1 or stage 2 diversion system (as applicable), and/or imported water released from the CDL to maintain flow within the FCWZ. The ability to maintain instream flow during the dry season is supported by hydrological analyses. Even in a hypothetical, complete drought year during which there is no inflow to Coyote Reservoir, there is adequate storage in Coyote Reservoir to maintain a steady 5 cfs release throughout the entire year (Schaaf & Wheeler & Black & Veatch 2019). Furthermore, storage in Coyote Reservoir at the beginning of May was greater than 7,000 AF in all years from 1999 to 2015, including three critically dry years. A release of 8 cfs from May 1 through November 1 would require around 3,000 AF of water, which would leave 4,000 AF or more for carryover to the next year, for contingency release during a dry November and December, or losses to evaporation.

The water bypassed and released through the dam diversion systems would be supplemented with imported water released via the CDL pursuant to the Construction Period Imported Water Releases for FCWMZ Conservation Measure. The 4 to 9 cfs that would flow through from Coyote Reservoir through the stage 1 or stage 2 diversion systems under normal operation of Coyote Reservoir with bypass flows would not be adequate to maintain streamflow through the FCWMZ during most years, accounting for losses due to evaporation and percolation. Therefore, pursuant to the Conservation Measure, Valley Water would release imported water at the CDL to maintain a flow of 10 cfs into the FCWMZ. The remainder of the 11 to 56 cfs of Cross Valley Pipeline water that will be needed during the dry season to maintain groundwater recharge and streamflow farther downstream will be released into Coyote Creek just downstream of the Ogier Ponds through the Cross Valley Pipeline Extension. Therefore, there will be times when flow downstream of Anderson Dam will be made up primarily or solely of bypassed native flow only and times when flows would be made up of combined bypassed native flow plus imported water releases from the CDL (FCWMZ) and Cross Valley Pipeline Extension (downstream of Ogier Ponds). Together, these releases will be sufficient during a typical year to support groundwater recharge and surface flow downstream in Coyote Creek, through Coyote Percolation Pond, to where streamflow would otherwise be perennial due to groundwater emergence and inflow from Lower Silver Creek and Upper Penitencia Creek.

Connection between Coyote Creek and San Francisco Bay under the Project construction period, as for FOCP, would depend on the amount of inflow from Fisher Creek, Lower Silver Creek, Upper Penitencia Creek and other inflow sources; and groundwater emergence, which typically supports perennial flow beginning between Montague Expressway and Berryessa Road. These inflows would allow surface flow to continue to San Francisco Bay and help prevent dry-back in the reaches of Coyote Creek between Ogier Ponds and the Highway 237 bridge. Valley Water will also implement a Dryback Monitoring Plan to assess conditions in Coyote Creek and inform management actions.

With the lack of storage to provide summer reservoir releases, the only flows downstream of Anderson Dam during the dry construction season will be what occurs naturally from upper Coyote Creek Watershed passed through Anderson Dam and the imported water releases from the CDL (released into the south channel) and the Cross Valley Pipeline Extension (released downstream of Ogier Ponds). Flows from the unaltered tributaries of Anderson Reservoir and Coyote Creek are expected to taper during each dry season and become negligible by season end.

In the dry season work window, flows downstream of Anderson Dam will likely be very similar to those during the Existing Conditions baseline. FOCP construction seasons to date (minus the initial 2020 drawdown to deadpool) are shown in **Table 3.4-11**. Flows recorded during the dry season work window under FOCP (existing conditions) are likely similar to the flows that will be available during the work window in the Project construction phase because flows during the work window are almost always below maximum conveyance capacity even for these early years of FOCP when the existing outlet can only pass up to 500 cfs, with 2023 being a potential rare exception due to above average precipitation through the entire wet season .

Table 3.4-11. Mean Daily Flow Per Month within the FCWMZ Measured at Madrone Gage 5082 (COYO9) for the In-Channel Construction Season

FOCP Year	Mean Monthly Flow Downstream of Anderson Dam (cfs)						
	Apr	May	June	July	Aug	Sept	Oct
FOCP Year 2 (2021)	46	52	23	10	14	30	36
FOCP Year 3 (2022)	13	12	19	19	15	20	12 [a]
FOCP Year 4 (2023)	452 [a]	NA	NA	NA	NA	NA	NA

Notes:

[a] Estimated from provisional data

Key: NA = Not Available at the time of preparation

Table 3.4-11 shows that flow releases from Anderson Dam and the CDL maintain flow within the FCWMZ during Existing Conditions between 10 cfs at the very low end (lowest level during drought) and 452 cfs at the very high end, as shown in April of the extremely wet 2023 water year. 2023 was a very wet year and flows that high are less likely to occur again during the Project (less than 10 percent probability). Given the extremes of the years recorded thus far for FOCP, it is most likely that flows in the FCWMZ will be somewhere in between these two extremes and most likely in the 10-23 cfs range. Based on the HCM instream flows study (Stillwater Sciences 2021), all flows in this range are anticipated to continue to provide plenty of suitable rearing habitat within the FCWMZ throughout the dry season work window.

In the wet season, precipitation-driven water discharges will be elevated compared with both existing conditions and Pre-FERC Order Baselines due to FOCP completion of the ADTP tunnel and increased outlet capacity <u>as well as the increased channel conveyance from the North Channel Extension (completed as part of FOCP)</u>. Conservation Measures are designed to accommodate the increased <u>Project</u> water discharges including <u>conveyance through</u> the North Channel <u>Reach</u> ~~Extension~~.

Wet-season flows under existing conditions and during Anderson Dam construction will include peaks in runoff from the northern branch tributaries associated with precipitation. As these flows are passed through Anderson Reservoir to Coyote Creek downstream, the shape of the downstream hydrograph (how flows change through time) will be more responsive to individual runoff events than the Pre-FERC Order Baseline, more closely approximating an unimpaired hydrograph <u>with increased flow variability</u> which may be a benefit to steelhead and their critical habitat, particularly migration conditions. In addition, <u>increased</u> flow variations associated with runoff events could boost natural processes such as sediment sorting and maintenance of aerated gravels that are important habitat for invertebrates (prey for rearing steelhead) and for steelhead spawning and would also mean that steelhead may experience wet season flows higher than the Pre-FERC Order Baseline or existing conditions (see Section 3.11, *Hydrology*) after completion of the Stage 2 Diversion ~~and the North Channel Extension~~<u>. Increased flow variability may also impair non-native fish populations benefitting steelhead as well as other native species.</u> By retaining the ability to store and release water through Normal Operation of Coyote Reservoir, bypassing flows through Anderson Reservoir to Coyote Creek, augmentation of streamflow in the FCWMZ using native water released through the dam, supplemented by imported water released through CDL, and additional downstream instream flow augmentation via the Cross Valley Pipeline Extension following its construction, Valley Water would maintain suitable habitat for rearing steelhead in the FWCMZ and reduce the potential for drying of Coyote Creek downstream of the FCWMZ due to drawdown of Anderson Reservoir and associated changes to flows during Seismic Retrofit construction relative to Pre-FERC Order Baseline. The Stage 2 Diversion will allow for greater streamflow fluctuations in Coyote Creek and more closely approximate an unimpaired hydrograph. Sufficient surface water flow is expected such that the impacts on fisheries resources, including steelhead, would not be significant due to changes in Project construction phase hydrology as compared to the Pre-FERC Order Baseline or existing conditions.

<u>Construction Phase Water –Quality - Dissolved Oxygen and Temperature During Dry Season and Drawndown Reservoir</u>

Water quality impacts the ability for steelhead to migrate, spawn, incubate, and rear. Water quality parameters that are important for assessing the impacts on this species include changes in temperature, DO (discussed in this section), and suspended sediment (discussed in the section below).

During the construction phase, when Anderson Reservoir is drawn down during the work window, the Normal Operation of Coyote Reservoir will provide flows that will mix with the flows from the other tributaries of Anderson Reservoir not controlled by any major dam, diversion, or reservoir, and will be conveyed to Coyote Creek downstream of Anderson Dam through either the Stage 1 or or Stage 2 Diversion structure (as applicable). These bypass flows may be supplemented by imported water releases via the CDL to assure releases of at least 10 cfs to maintain sufficient flows within the FCWMZ. Imported water releases of up to 10 cfs may be passed through chillers prior to release to Coyote Creek from the CDL in attempt to maintain temperatures within the FCWMZ of 18 °Celsius during the summer rearing period. The continuation of these bypass flows supplemented by imported water releases, and the use of chiller will minimize reductions in water quality, mainly DO and temperature, within the FCWMZ that would otherwise occur during the construction phase dry season.

To date, Valley Water collected DO and temperature data for the first 3 years of FOCP. During that time, DO has not become unsuitable for steelhead and only July and August 2021 came close to the upper limit of suitable rearing conditions for temperature (greater than 75 °F [23.9-°C]) for juvenile steelhead at the Madrone Gage 5082 in the FCWMZ. Valley Water has also documented steelhead successfully rearing through the summer despite times of temperatures above the “suitable” range (Valley Water 2021a, 2021b, 2022). These temperatures were recorded for releases from the dam and/or CDL that were not chilled; therefore, temperatures are likely higher than the temperatures of instream flows that would occur during Seismic Retrofit construction when the chillers are installed and functioning, particularly in temperature-limiting months in the dry season. Therefore, water temperatures in the primary rearing area from the CDL to Ogier Ponds would be the same or lower during the Project. Accordingly, these conditions would be better for steelhead when compared with the existing conditions baseline.

Based on estimates generated from temperature records from 1999 to 2019, the average temperature of imported water that would be released to Coyote Creek downstream of Anderson Dam reaches nearly 64.4 °F (18 °C) before the end of June and exceeds 68 °F (20 °C) from July through October (Valley Water, unpubl. data). During construction, if imported water releases are determined to be too warm for *O.* mykiss or likely to produce temperatures in the FCWMZ that exceed 18 °C, chillers installed under the FOCP would be used to cool up to 10 cfs of imported water prior to release via the CDL into Coyote Creek to retain cooler temperatures within the FCWMZ. Additional un-chilled imported water would be released via the Cross Valley Pipeline Extension downstream of Ogier Ponds to continue to provide surface flow for groundwater recharge below the FCWMZ. A total of three chillers (two chillers would be used with a third chiller available in reserve) would take an 800-amp current to chill a combined flow of up to 10 cfs by up to 7 °C to provide cooler temperature flow from the CDL to the FCWMZ. Therefore, chillers will allow colder water from the CDL than was feasible under the Pre-FERC Order Baseline. Also, downstream dryback would be reduced and groundwater recharge would continue through releases at the Cross Valley Pipeline Extension and would incidentally support aquatic and riparian habitats resulting in no additional adverse impacts from water temperature during Project on steelhead and benefits to rearing steelhead in the dry season relative to Pre-FERC Order baseline.

In addition to using electric chillers to minimize temperature impacts on steelhead, Valley Water would continue to monitor temperatures and DO at the base of the dam (COYO10), Madrone Gage 5082 (COYO9), upstream of Ogier Ponds (COYO8), and downstream of the FCWMZ. ~~They~~ Valley Water would also monitor for rearing juveniles in the FCWMZ, migrating adults at the Coyote Percolation Dam, and eDNA in the FCWMZ. This provides Valley Water with insight on the distribution of steelhead in the reach. According to the Fish Rescue and Relocation Plan, fish rescue would be initiated if a MWAT of 75 °F (24 °C) is reached or predicted to be reached in the entire FCWMZ with consultation from state and federal resource agencies (see the *Construction Monitoring* section for more discussion). Other factors, such as DO levels less than 7 mg/l will also be considered in determining the need for a fish rescue but, in general, the water quality data gathered during FOCP before chillers were implemented indicate that temperature and DO maximums should not be exceeded during Project construction. Furthermore, this monitoring data collected prior to and during Seismic Retrofit construction would be used in ongoing TWG discussions to consider in coordination with the regulatory agencies the risks of capture and relocation with the risks of allowing steelhead to remain in the FCWMZ under suboptimal conditions and determine the best course of action to minimize any unanticipated adverse effect of increase temperature or reduced DO on fisheries.

Under existing and Pre-FERC Order Conditions steelhead rearing is limited downstream of the FCWMZ, due to high water temperatures associated with the presence of the Ogier Ponds complex. Therefore, currently steelhead primarily use the habitat within the FCWMZ. Habitat within the FCWMZ will further be enhanced through restoration activities and will continue to support rearing.

Through the use of Coyote Reservoir bypass, imported water releases to the FCWMZ, use of the chillers for CDL releases, downstream Cross Valley Pipeline Extension releases, water quality monitoring and determination of flow and fish management actions in coordination with the Technical Working Group, and the implementation of the Fish Rescue and Relocation Plan when necessary, Project construction phase reservoir drawdown and operations impacts from changes in DO and temperature would be less than significant on the steelhead population.

Construction Phase Water Quality - Sediment Transport During Wet Seasons and Spring Drawdown

During the wet seasons of Years 1 and 2, the Stage 1 diversion would be in place allowing for a faster drawdown of up to 2,500 cfs, a considerably higher conveyance capacity than the up to 500 cfs capacity under the Pre-FERC Order Baseline. Following the Year 2 dry construction season, the Stage 2 diversion would be constructed, allowing for an even faster drawdown of up to 6,000 cfs, a considerably higher conveyance capacity than Years 1 and 2 as well as the Pre-FERC Order Baseline. Drawing water down faster and keeping a lower elevation in the reservoir so that in-reservoir sediments are exposed to precipitation and flow would result in increased sediment erosion and transport downstream during drawdowns and high flows for a period of days following the precipitation events. This section looks at the impacts on steelhead of increased sediment in Coyote Creek due to increased erosion and sediment transport when bypassing flows through the drawn-down reservoir during the wet season, and during spring drawdowns relative to the Pre-FERC Order Baseline.

CCC steelhead have evolved in flashy watersheds that frequently have high suspended sediment and associated turbidity during and following storm events, particularly the first storm events of the water year. Suspended sediment concentration is the concentration of sediment particles [8] suspended in water, usually measured in mg/L. Turbidity is a measure of water clarity (how much light is scattered in a liquid). Turbidity is related to suspended sediment and is usually measured as nephelometric turbidity units (NTU). Turbidity is easier to measure in the field and

---

[8] Suspended sediment concentration is a measure of the amount of organic and inorganic particles in water. TSS which is ~~the~~ also a measure of the concentration of ~~all~~ organic and inorganic particles in water is ~~also~~ used sometimes instead of suspended sediment concentration. TSS only measures the weight of solids captured on a filter which can result in larger particles not being measured, therefore suspended sediment concentration is generally considered more accurate. The EIR uses suspended sediment concentration but ~~suspended sediment concentration correlates with~~ TSS also measures particles in water so either one could be used when discussing impacts to fish.

is often used as a proxy for relative levels of suspended sediment concentration. However, when discussing impacts, it is important to distinguish the two while acknowledging their relationship.

Turbidity alone does not impact fish gills or fish physiology directly but can result in the decrease of visual predation efficiency. Some fish have been shown to be attracted to turbid water over clear water, most likely to avoid predators or to conceal themselves from their prey as they are visual predators (Gradall and Swenson 1982, Cyrus and Blaber 1992, both as cited in Wilber and Clarke 2001). While turbidity can reduce foraging success, low levels of turbidity can function as cover to reduce predation in riverine, estuary, and nearshore marine environments (Gregory and Levings 1998, Wilber and Clarke 2001, Gadomski and Parsley 2005). Therefore, increased turbidity can be either an adverse or beneficial impact depending on the context. ~~When a fish is a visual predator, turbidity decreases foraging success and when the fish is prey, turbidity decreases predation risk; therefore, increased turbidity can be adversely impactful or beneficial depending on the context.~~

Suspended sediment can affect a fish’s gills and/or physiology directly (see reviews by Newcombe and MacDonald 1991, Newcombe and Jensen 1996, Kemp et al. 2011, Kjelland et al. 2015). Fish have evolved to tolerate different ranges of suspended sediment concentration depending on their specific habitat conditions during different life history stages. However, every fish has an upper maximum limit of suspended sediment concentration exposure at which the suspended sediment affects the fish’s gills and physiology ranging from minor physiological stress to injury and mortality with several levels of severity in between (Newcombe and Jensen 1996; Appendix F). When mortality occurs, it is usually due to either asphyxia because the gills are too badly damaged or clogged with particles that the fish cannot breathe enough oxygen to maintain essential life functions, or due to injured gills being a source of infection. Naturally, fish try to avoid this consequence and seek refuge in places where suspended sediment concentration is lower and/or perform a behavior called “coughing” where the fish opens its mouth wide and forces water through the gills at higher velocities to try to dislodge the particles from the gills. Fish can also respond to higher suspended sediment concentration by adjusting their gill morphology (e.g., producing excess gill mucous and growing additional protective cells; Hess et al. 2015), and it is assumed that fish have also evolved different gill morphologies or physiological adaptations to tolerate relevant ranges of suspended sediment concentration for their habitat.

Information on both concentration and duration of suspended sediment is important for understanding the severity of its effects on salmonids (Newcombe and MacDonald 1991). Herbert and Merkens (1961) stated that “there is no doubt that many species of fresh-water fish can withstand extremely high concentrations of suspended solids for short periods, but this does not mean that much lower concentrations are harmless to fish which remain in contact with them for a very long time.” Effects of suspended sediment on fish can also be exacerbated by other stressors (e.g., high water temperature and disease) (Redding et al. 1987, Servizi and Martens 1991).

As described in Section 3.4.3.1, this analysis used sediment transport modeling to estimate the likely exposure levels (derived from duration and magnitude of elevated suspended sediment) which was then translated into the likely impacts predicted for exposed steelhead in Coyote Creek downstream of the dam under varying conditions (back to back 2-year storm events, constant inflow to the reservoir and outflow to Coyote Creek, 2-year storm events, and/or 5-

year storm events). The impact analysis described here is a summary of the results with the more detailed technical methods and analyses described in Appendix F.

During and for a short time immediately following simulated back-to-back 2-year or greater precipitation events in the wet seasons of Year 1 and Year 2, if adult steelhead choose to migrate up Coyote Creek and remain there, they would experience minor physiological stress, increased rates of coughing, and increased respiration rates. Temporary, minor physiological stress usually has no long-term impacts on an animal and is an adaptive response that allows animals to cope with normal, stressful events (Sapolsky 2021 ~~2004~~). However, minor physiological stress and increased respiration rates across long durations can result in sublethal impacts like impaired reproduction and increased susceptibility to disease and parasites. In recent years, no adult steelhead have been observed in Coyote Creek and adult steelhead could behaviorally regulate their exposure and choose not to enter and migrate up Coyote Creek, potentially straying to a different watershed. They could also migrate up Upper Penitencia Creek, or they may continue to migrate up Coyote Creek and reproduce there. Some steelhead die after spawning and some return to the ocean and can reproduce again in Coyote Creek or select a different watershed to spawn. It is not entirely clear what the impacts of prolonged minor physiological stress and increased respiration would be, but some decrease in reproductive fitness is probable due to increase sediment and erosion compared with the Pre-FERC Order Baseline.

Under modeled back to back 2-year or greater storm events with the Stage 1 diversion, incubating eggs could experience 0-20 percent mortality (Appendix F) and juveniles may experience minor physiological stress during and for a short period immediately following precipitation. Like adults, minor physiological stress over short durations would have little impact on juveniles, but prolonged physiological stress even if “minor” could result in sublethal effects such as slower growth, decreased foraging efficiency, and increased susceptibility to disease and parasites potentially decreasing their overall fitness during their lifetime. However, juveniles may benefit from higher turbidity through decreased predation pressure as long as the associated suspended sediment is not too high to cause prolonged physiological stress (Newcombe and Jensen 1996, Gregory and Levings 1998, Wilber and Clarke 2001).Collectively, increased suspended sediment under back to back 2-year storm events in the wet seasons of construction Years 1 and 2 and could decrease productivity of the steelhead population in Coyote Creek due to these sublethal effects on spawning adults, juveniles, and effects on incubating eggs compared to Pre-FERC Order Conditions.

Under the Pre-FERC Order Baseline, conditions supported abundant spawning and rearing habitat in Coyote Creek and the project may result in increased mortality of eggs and an overall decrease in productivity of the steelhead population due to increased sediment transport during seismic retrofit construction. Steelhead utilizing Upper Penitencia Creek would not be subjected to the increased sediment transport from Seismic Retrofit construction so there would still be habitat for adults, egg incubation, and rearing in the watershed that would not be subject to these stresseors. Although low flows in recent years have resulted in estimated low abundance of *O. mykiss* in Upper Penitencia Creek, the species is persisting and a high abundance was observed in the Arroyo Aguague in 2022 and 2023. Specifically, flows in Upper Penitencia Creek were low during the 2020-2022 extreme drought. This time period represents extreme conditions and is one of the driest periods in the historical rainfall record. The conditions observed in Upper Penitencia Creek during those years are thought to be worse case scenario and the species remained. Heavy rains in the winter of 2023 improved habitat conditions and increased *O. mykiss* densities in the system, including within Upper Penitencia Creek, greatly (Valley Water 2024). The physical habitat conditions at all sites in summer and fall of 2023 were suitable to support *O. mykiss* and capture of fish in their first and second year, indicating that conditions supported some level of rearing even during the extreme drought conditions (Valley Water 2024).

During the wet season in Years 3, 4, 5, 6, and 7, the reservoir would be allowed to fill up to elev. 467 feet and the Stage 2 diversion would be used to maintain the reservoir at that elevation. During constant inflow to the reservoir, erosion of sediment, and outflow to Coyote Creek in December through April, migrating adult steelhead could experience increased respiration rates, coughing, and minor physiological stress (Appendix F) due to sediment in flows. For the reasons outlined for the wet seasons of Years 1 and 2, some decrease in reproductive fitness is possible, but impacts to adults would not be substantial.

Under modeled constant inflows to the reservoir, erosion of sediment, and outflows to the creek, incubating eggs could experience 0-20 percent mortality (Appendix F) and juveniles may experience minor physiological stress. Like adults, minor physiological stress over short durations would have little impact on juveniles, but prolonged physiological stress even if "minor" could result in sublethal effects such as slower growth, decreased foraging efficiency, and increased susceptibility to disease and parasites potentially decreasing their overall fitness during their lifetime. However, juveniles may benefit from higher turbidity through decreased predation pressure as long as the associated suspended sediment is not too high to cause prolonged physiological stress (Newcombe and Jensen 1996, Gregory and Levings 1998, Wilber and Clarke 2001).

Under the Pre-FERC Order Baseline, conditions supported abundant spawning habitat in Coyote Creek, collectively, increased suspended sediment under constant flows in the wet seasons of construction would decrease productivity of the steelhead population in Coyote Creek during Project wet seasons (Years 3-7) due to egg mortality, sublethal effects on adults, and minor physiologeical stress to rearing juveniles. Redds in Upper Penitencia Creek would not be subjected to the increased sediment transport from Seismic Retrofit construction so there would still be incubating eggs in the watershed that would have a lower mortality rate.

Constant inflow to the reservoir was modeled as 180 cfs, which would often be higher than wet season baseflows but could occur for a prolonged time following a high flow event (e.g., the tail end of a hydrograph or the time between flow peaks from different storm events). While this is possible, the likelihood is low, so impacts are likely overestimates. Also, even with mortality of eggs, steelhead lay enough eggs that there could be enough fry to occupy the available habitat even with a large percent of mortality from incubating eggs so a decrease in survivorship of eggs may not be limiting to the population overall.

During 2-year and 5-year precipitation events, if adult steelhead choose to migrate up Coyote Creek and remain there, they would experience minor to moderate physiological stress, increased rates of coughing, and increased respiration rates due to the increase sediment concentration associated with the project. These effects would be temporary and sublethal and would likely result in some impaired reproduction. Juveniles would experience moderate physiological stress and the effects would be temporary and sublethal but, prolonged physiological stress even if "moderate" could result in sublethal effects such as slower growth, decreased foraging efficiency, and increased susceptibility to disease and parasites potentially decreasing their overall fitness during their lifetime. As such, overall reproductive fitness would likely decrease as compared to the Pre-FERC Order Baseline, but sediment concentration data are not available for Pre-FERC Order Baseline, so a direct comparison cannot occur. Incubating eggs could experience 0-20 percent mortality. In addition, 2- and 5-year flow events could lead to increased pool depths, reduced spawning gravel quantities, reduced access to low-terrace floodplain habitat from increased channel incision, and reduced benthic macroinvertebrate (BMI) production but would only occur in limited areas within Coyote Creek. Lower quality spawning habitat and reduced BMI production (food supply for rearing juveniles) may reduce the survival of incubating eggs as well as the growth of fry and juveniles rearing within these limited areas, but steelhead would not be impacted in this way throughout most of the creek, and the Live Oak Restoration Project would have enhanced rearing habitat prior to the start of the Project, buffering this impact further. Collectively, increased suspended sediment under precipitation events in five wet seasons of construction would decrease productivity of the steelhead population in Coyote Creek during Seismic Retrofit construction (Years 3-7) but the impact would not be substantial for the population in the watershed as a whole and impacts would be less than significant.

Although it would not be possible to always avoid temporal impacts to steelhead and their habitat in the short-term, Valley Water would conduct suspended sediment monitoring continuously and sediment deposition monitoring annually and ~~the~~ gravel augmentation ~~program and general Sediment Augmentation Program~~ initiated during FOCP through the Live Oak Restoration Project, which will be in place before this Project starts. The gravel ~~and sediment~~ augmentation ~~programs~~ would be maintained during seismic retrofit construction of this Project. In addition, Valley Water proposed to implement post-construction sediment and sediment deposition monitoring, Live Oak Restoration Reach and Ogier Ponds CM maintenance, North Channel Reach maintenance, ongoing Sediment Augmentation Program ~~sediment augmentation~~, and adaptive management. Therefore, construction phase sediment transport impacts would be minimized through the ongoing monitoring and augmentation programs during and after construction over the long term. Because spawning gravels ~~and sediment~~ would be replaced as needed based on the monitoring throughout the Seismic Retrofit construction years and the programs would continue into the future through the Project and FAHCE AMP and SMP, over the long-term, the temporary sediment transport impacts during Seismic Retrofit construction would not only be remediated, but used to restore spawning habitat to an improved condition.

In spring (April) of Years 3, 4, 5, and 6, drawing the reservoir down to elevation 450 feet would occur with the Stage 2 diversion allowing up to 6,000 cfs to pass directly through to downstream. The drawdown from 467 feet to 450 feet would be a much smaller magnitude change compared to the change from deadpool to 450 feet. Storm events are less likely in April (less than 10 percent) and become less likely into late spring and summer, but smaller storm events may occur, and the modeling simulated a 2-year storm event, in addition to constant inflows in the absence of a storm event. Under constant inflow as well as the storm events, if migrating adults are present in April (the end of the migration season), they could experience moderate physiological stress, but effects would be sublethal and temporary and most adults would have already migrated and spawned by this time. Juveniles could experience moderate physiological stress under both elevated constant inflow and storm event conditions. Moderate physiological stress in juveniles for a prolonged period could result in sublethal effects such as slower growth, decreased foraging efficiency, and increased susceptibility to disease and parasites decreasing their overall fitness during their lifetime. However, juveniles may benefit from decreased predation pressure associated with higher turbidity because they would be less visible to predators in the more turbid water and the increase in flows downstream during the drawdown would encourage and support outmigration of smolts. Any smolts that outmigrated would have a more limited exposure duration to the elevated suspended sediment and therefore less impacts. Incubating eggs could experience 0-20 percent mortality representing a worst case scenario in the FCWMZ. Collectively, increased suspended sediment under constant flow and storm events during spring would decrease productivity of the steelhead population in Coyote Creek during Years 3, 4, 5, and 6 of the Project adding to the short-term impacts identified for wet seasons above but, due to the reasons outlined for wet seasons, these impacts would be less than significant on the population as a whole in the watershed. In the long term, impacts would be reversed and there would be a net benefit to the steelhead population from the gravel and sediment augmentation programs associated with maintaining the Live Oak Restoration Project and the Ogier Ponds CM and informed by the construction phase sediment monitoring, and ongoing Sediment Deposition Monitoring that will occur annually during these construction years with an aim to detect and reverse any impacts of sediment deposition on spawning gravels in the FCWMZ as quickly as possible.

Following Year 6, the reservoir would start to refill via inflows and, if possible, imported water up to the new maximum level. Once the reservoir fills to operable levels, exposed sediments would be covered by reservoir water, and then the FAHCE rule curves would be initiated. The refilling of the would occur over 1-2 years depending on the watershed inflows. With the reservoir refilled, suspended sediment would decrease during constant inflow or precipitation events because the full reservoir would ~~not~~ have less exposed erodible sediment and releases would decrease so conditions would return to near-Pre-FERC Order Baseline and would not be expected to impact steelhead further.

Overall, sediment transport in instream flows during Seismic Retrofit construction could result in periodic, temporary less than significant impacts to steelhead in the short-term (during the construction phase) during and immediately following wet season precipitation events and during the spring reservoir drawdowns during Seismic Retrofit construction. Suspended sediment monitoring, sediment deposition monitoring, the gravel and sediment augmentation programs, and the Ogier Ponds CM would prevent the long-term degradation of spawning habitat and would reverse the spawning and productivity impacts, resulting in less than significant impacts, and a net benefit to the steelhead population and its habitat in the long-term.

Non-native Species Effects During Construction Phase Drawdown and Operations

Some aquatic non-native species prey on juvenile steelhead and compete for habitat and food resources (Carey et al. 2011, Thompson et al. 2012). The non-native fish species present throughout Coyote Creek that pose the most significant risk to native fish and wildlife are the predatory largemouth bass (*Micropterus salmoides*), spotted bass (*Micropterus punctulatus*), green sunfish (*Lepomis cyanellus*), bluegill (*Lepomis macrochirus*), crappie species (*Pomoxis* spp.), and catfish species (*Ictalurus* and *Ameiurus* spp.) ~~.~~Reservoir drawdown during Seismic Retrofit construction may increase the rate of introduction of new non-native species from upstream of the dam to downstream of the dam and may continue to be introduced ~~i~~through imported water releases.

Several non-native fish species occur in Anderson Reservoir including competitors and predators. A fyke trap was deployed at the outlet of Anderson Dam during late September through late November 2020 and from March through April 2021 to monitor fish species passing from Anderson Reservoir downstream to Coyote Creek during FOCP dewatering. The fyke net captured nearly 300 non-native largemouth bass, and a few black crappie, bluegill, common carp, threadfin shad, and inland silversides potentially leaving Anderson Reservoir (Valley Water 2021d ~~2021c~~). However, all of the species captured already occurred in Coyote Creek and the FCWMZ under Pre-FERC Order Baseline so no new species are predicted to be released from Anderson Reservoir to Coyote Creek during Project construction.

The use of chillers to cool the FCWMZ would reduce the suitability of conditions for non-native species while promoting suitability for special-status species. For example, largemouth bass prefer temperatures for rearing between 25–30 °C (Moyle 2002), which are unlikely to occur within the FCWMZ, and likely to occur in Ogier Ponds and further downstream. Habitat conditions downstream will likely remain the same as Pre-FERC Order Conditions and should not provide additional habitat for non-native species. Additionally, Valley Water would dispatch non-native fish trapped during monitoring or dewatering activities. Therefore, impacts from the release of non-native species from Anderson Reservoir downstream to special-status fish would be less than significant compared with the Pre-FERC Order Baseline.

Instream Flows During Construction Summary

Overall, instream flows during construction would maintain steelhead throughout the entire construction phase of the Project because expected flow depths, temperatures, and DO are within a range that can support steelhead migration, spawning, incubation, and rearing in the FCWMZ throughout Seismic Retrofit construction. This is made possible by the Normal Operation of Coyote Reservoir, Construction Period Imported Water Releases and use of chillers for such releases to the FCWMZ, and Cross Valley Pipeline Extension releases to provide in-stream flow downstream of the CWMZ~~, and operation of the North Channel Extension for high flow releases~~. Minimization of these impacts on steelhead would also be aided by the Maintenance Activities at Live Oak Restoration Reach and North Channel Reach, and offset by the improvement of creek habitat associated with the Ogier Ponds CM, and the implementation of the CWMZ Sediment Augmentation Program. Sediment transport would be the main impact to instream flows and fisheries habitat during construction phase drawdown and operations. causing sublethal physiological stress in adults and juveniles and some (up to 20 percent) mortality of incubating eggs. Sublethal physiological stress over short durations would have little impact on juveniles, but prolonged physiological stress could result in sublethal effects such as slower growth, decreased foraging efficiency, and increased susceptibility to disease and parasites potentially decreasing their overall fitness during their lifetime. Similarly, if adults chose to migrate during periods of high suspended sediment loads they would experience physiological stress, increased rates of coughing, and increased respiration rates. Physiological stress and increased respiration rates across long durations can result in sublethal impacts like impaired reproduction and increased susceptibility to disease and parasites These effects would in turn decrease productivity of the steelhead population during construction compared with the Pre-FERC Order Baseline, resulting in short-term less than significant impacts.

Although non-native species could be introduced as a result of imported water releases during construction, imported water releases that may contain non-native species would not be greater than releases compared with the Pre-FERC Order Baseline. In addition, the ability to release imported water from a new location downstream of the CWMZ as a result of FOCP construction of the Cross Valley Pipeline Extension would reduce imported water and related non-native invasive species introduced into the FCWMZ as compared to Pre-FERC Order conditions.

Construction phase suspended sediment, sediment deposition monitoring throughout Project construction and during post-construction, and implementation of the following Conservation Measures would minimize and remediate these impacts: Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach, implementation of the Ogier Ponds CM to enhance and enlarge fry and juvenile rearing habitat and improve migration, implementation of the Phase 2 Coyote Per Dam to improve migration, implementation of the Sediment Augmentation Program in the CWMZ combined with Maintenance of the North Channel Reach ~~Extension~~ to protect portions of CWMZ from scouring flows, post-construction implementation of FAHCE rule curves and flows as well as adaptive management of all of these Conservation Measures would restore, increase, enhance, and maintain spawning and rearing habitat and reverse temporary, periodic, construction phase sediment transport impacts.

Conservation Measures Construction

Conservation Measures that constitute physical improvements to be constructed are analyzed here and are: Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, Maintenance of Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach, Sediment Augmentation Program, and Phase 2 Coyote Percolation~~.~~ Dam CM (see Section 2.6, *Conservation Measures Construction*).

Ogier Ponds Conservation Measure

The Ogier Ponds CM would restore approximately 6,500 linear feet of river channel and connect the channel to the floodplain and is predicted to enhance over 67,000 square feet of steelhead rearing habitat (Valley Water and Stillwater Sciences 2024). Construction activities include creating a defined creek channel by separating the existing hydraulic connection between Coyote Creek and Ogier Ponds, returning the creek to a riverine channel, and adding ecological enhancements to the channel and floodplain. In addition to creating a large amount of rearing habitat, separating the Ogier Ponds from Coyote Creek would benefit steelhead and their habitat by improving water quality via lowering temperatures in the creek downstream of the ponds. It would also eliminate migration delays that likely occur under existing conditions when migrating salmonids arrive at the slack waters of the current ponds. Although a managed hydrological connection (through weirs) would be maintained between the Creeks and the ponds to avoid degradation of pond water quality, the Ogier Ponds CM would allow the full CWMZ as defined in the FAHCE *Settlement Agreement* to function. Because the ponds would no longer result in the significant warming of the creek flow, the existing elevated temperature of creek water downstream of the CWMZ would also be colder which would further benefit steelhead in Coyote Creek.

Under both the Pre-FERC Order Baseline and the existing conditions baseline, it was determined that the water from Ogier Ponds is often too warm for steelhead rearing, the slow water within the ponds may discourage migrating steelhead from swimming into or through the ponds, and the risk of predation increases in the pond environment. The separation of the ponds from the main channel would allow steelhead to migrate more efficiently both up and downstream within Coyote Creek or with reduced predatory pressure and improved water quality following completion of the Conservation Measure construction.

While the Ogier Ponds CM would provide substantial benefits to steelhead once complete, the construction of the Conservation Measure would have short-term impacts to rearing juveniles that may be present during construction during dewatering and diversion activities. Implementation of the in-channel work window and BMP BI-2 will minimize impacts to adult steelhead and spawning activities during dewatering and impacts from increased suspended sediment in the channel by restricting dewatering activities and routine vehicle use in-channel to times when steelhead are not spawning and adults are not present in the system. This work window minimizes impacts to migrating steelhead because adults immigrate December through April and smolts outmigrate February through May. However, rearing juveniles occur in Coyote Creek year-round. Coffer dams upstream and downstream of the Ogier Ponds work area would be removed at the end of each dry season providing fish passage during the wet season. This would avoid and minimize adult and smolt migration impacts as well as impacts to movement of fry and rearing juveniles.

Construction of the Ogier Ponds CM would begin in Year 6 and end in Year 8, which would minimize overlap of this project with Seismic Retrofit construction. Construction would occur over a three-year period, during the in-channel work window. Construction of the Ogier Ponds CM would require dewatering of the pond areas to be filled, diversion of creek flow around the work area, and control of groundwater to minimize expected seepage into the work areas, which would be implemented annually during the in-channel work window (i.e., three times during the construction of the Ogier Ponds CM).

Rearing juveniles occur in Coyote Creek year-round. Localized dewatering during construction activities has the potential to strand steelhead or trap them in pools subjecting them to increased predation pressure or water quality degradation; therefore, under the dewatering and aquatic species rescue and relocation plan for the Ogier Ponds CM, *O. mykiss* would be excluded with block nets and/or captured and relocated prior to and during dewatering for construction. Capture methods would include backpack electrofishing, seining dip netting and/or capturing by hand. Impacts would include stunning, netting, capturing, and handling, causing acute physiological stress. Injury or mortality can happen occasionally but is rare, as most steelhead tolerate capture and handling. Two fish rescues have been conducted under FOCP according to the Fish Rescue and Relocation Plan approved by NMFS resulting in the capture of 235 *O. mykiss* (~~Valley Water and Stillwater Sciences 2020~~, Valley Water 2020d; Valley Water 2021c ~~2021h~~). During these rescues, Valley Water documented mortality of 4 individual *O. mykiss* (less than 2 percent of captured *O. mykiss*). Expected acute physiological stress during rescue and relocation would be a lesser impact than likely mortality due to stranding, predation, and/or deteriorating water quality conditions if rescue and relocation during localized dewatering were not implemented.

BMPs GEN-35 and WQ-3, as well as AMM-17, will protect steelhead from being injured or killed during dewatering activities or pumping streamflow around the work site by using pumps and intake hoses screened, according to NMFS and CDFW criteria to prevent uptake of fish and other vertebrates. The dewatering and aquatic species rescue and relocation plan for the Ogier Ponds CM would reduce impacts of fish stranding during dewatering by implementing a fish rescue and relocation effort during localized dewatering. The Invasive Species Monitoring and Control Plan and AMM-91 could reduce predation pressure and/or competition from nonnative fish, crayfish, American bullfrogs, and red-eared sliders at least in the short-term (long term benefits are less likely unless eradication is achieved). BMP BI-11 and AMM-90 will minimize attracting predators to the work site by requiring that trash be removed daily from the construction area.

Construction activities including vegetation removal on the banks, potential excavation of fill material in proximity to the ponds, filling in Ponds 1 and 5, partially filling Ponds 2 and 4 ~~5~~, constructing an earthen berm, installing overflow weirs, and restoring the Coyote Creek Channel have the potential to degrade water quality downstream of the work area due to increased suspended sediment, the potential for release of other pollutants or materials in the water which could impact rearing steelhead located downstream of the Ogier Ponds, although most rearing habitat is upstream of Ogier Ponds. Diesel generators that would be used to pump groundwater from the work area have the potential to impact water quality and aquatic species. BMPs GEN-35 and WQ-3 will minimize pollution from diesel generators to impact water quality by maintaining and operating pumps according to manufacturer specifications and monitored to prevent low- or high-water conditions. BMPs GEN-20 and WQ-16, as well as AMM-66, AMM-84, and AMM-97, will reduce sediment entering the channel from the work area during precipitation events by installing erosion control measures (e.g., silt fences, straw bales, etc.) and visually inspecting erosion control measures during and following extended storm events. BMPs GEN-26, GEN-31, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, and AMM-11, will minimize the pollution from vehicle fluids or other oily, greasy, or sediment-laden materials that could enter the creek from the work area by maintaining clean conditions at work sites, keeping spill kits available onsite to clean up any accidental spills, training personnel to properly use spill kits, fueling and cleaning vehicles and equipment off site, keeping vehicles maintained and clean, and inspecting vehicles and equipment daily for leaks prior to initiation of work. BMP WQ-15 will protect steelhead downstream of the work area from impacts of degraded water quality by keeping any oily, greasy, or sediment-laden substances away from places they may enter the waterway and monitoring water turbidity changes downstream of the work area and any discharge points.

Staging and stockpiling areas associated with Ogier Ponds CM construction could introduce sediment to the channel during precipitation events. Pollution could also be introduced from vehicles and equipment in staging and stockpiling areas. If exposure to increased sediment and pollution was high enough and for a long enough duration, steelhead could exhibit behavior changes (moving downstream where pollution is more diluted), injury, illness, or mortality. BMPs GEN-21 and WQ-4, as well as AMM-66, AMM-67, AMM-68, AMM-84, and AMM-97, will reduce sediment entering the channel from staging and stockpiling areas by covering sediment piles or surrounding the piles with erosion control measures, filtering runoff, limiting the length of time materials can be stockpiled, and not placing sediment where it could spill into water bodies or storm drains. BMPs GEN-26, GEN-31, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, and AMM-11, will minimize the pollution entering the channel by maintaining clean conditions at staging and stockpiling areas, keeping spill kits available onsite to clean up any accidental spills and training personnel to properly use spill kits, cleaning vehicles and equipment off site, keeping vehicles maintained and clean, inspecting vehicles and equipment daily for leaks prior to initiation of work, and utilizing secondary containments when fueling vehicles and equipment in staging and stockpiling areas.

Cofferdam installation and diverting water around the work area would restrict juvenile rearing habitat and limit access to the FCWMZ upstream of Ogier Ponds. BMPs GEN-35 and WQ-3, as well as AMM-17, AMM-20, AMM-23, and AMM-24, will protect steelhead from being injured or killed through the diversion of water around the site by using pumps and intake hoses screened according to NMFS and CDFW criteria to prevent uptake of fish and other vertebrates, limiting the extent of the dewatering area, discharging water in a non-erosive manner, removing dewatering materials, restoring normal flows as soon as feasible after work is complete, and utilizing properly sized bypass pipes to prevent increases in temperature and decreases in DO.

Clearing and grubbing would remove vegetation and roots from the floodplain in preparation for excavation of the channel leading to some loss of habitat complexity for steelhead; however, adequately sized trees would be kept in place whenever feasible and, once the channel is reestablished in that area, the riparian corridor would be revegetated with native plants, benefiting fish habitat in the newly established channel.

The goal of the Ogier Ponds Restoration Project is to remove all fish passage impediments created by the ponds, including temperature and predation increases, by restoring approximately 6,500 ~~over 6,400~~ feet of channel to mimic riverine conditions observed in Coyote Creek upstream of the ponds. Based on the area per unit length of channel of suitable rearing area observed in the Habitat Criteria Mapping study directly upstream of Ogier Ponds, this would result in creation of over 67,000 square feet of suitable juvenile rearing habitat, and over 33,000 square feet of shallow water for fry rearing in inundated margin habitat at typical spring and summer flows (approximately 30-50 cfs) (Valley Water and Stillwater Sciences 2024). Based on the predicted increases in spawning habitat modeled to be achieved in the Live Oak Restoration Project scaled to the Ogier Restoration reach length, there is also a goal to create over 20,000 square feet of suitable spawning habitat.

Overall, short-term adverse impacts to steelhead could occur from fish rescue during dewatering and migration delay managed by proposed BMPs; impacts would be less than significant-. Over the long term, the Ogier Ponds CM would benefit steelhead by improving natural creek functions, adding and enhancing spawning and rearing habitat, improving water quality, and enhancing fish passage.

Maintenance of the North Channel Reach ~~North Channel Maintenance and Extension~~

~~Construction activities~~ Activities associated with the Maintenance of the North Channel Reach ~~Extension~~ would occur during the in-channel work window ~~of Year 1~~ as needed. Most maintenance activities would occur in dry areas with no water and only a few activities may ~~and would~~ include minor and localized dewatering of any remaining pools ~~and grading in the channel~~. Implementation of dewatering and aquatic resources rescue and relocation plan and BMP BI-2 will help protect steelhead from stranding during dewatering and from impacts from increased suspended sediment in the channel by restricting in-channel construction activities to the dry season work window-, having a plan for native fish rescue and relocation, and minimizing equipment driving in the stream bed. The work window minimizes impacts to migrating steelhead because adults immigrate December through April and smolts outmigrate February through May. However, rearing juveniles occur in Coyote Creek year-round. Prior to the start of ~~construction~~ activities associated with the North Channel maintenance ~~Extension~~, the North Channel may be dry so, in that case, no steelhead would be present and there would be no adverse impacts. However, if there is water in the North Channel and rearing steelhead are present, localized dewatering during ~~construction~~ maintenance activities could strand steelhead or trap them in pools, subjecting them to increased predation pressure or water quality degradation. Therefore, *O. mykiss* would be excluded with nets and a cofferdam would be built at the lower limit ~~of the backwater~~ to keep water from entering the work area or native fish would be relocated from pools that would then be pumped out before maintenance activities start. An agency-approved aquatic species rescue and relocation plan for the North Channel

Maintenance ~~Extension Project~~ would reduce impacts of fish stranding during dewatering by implementing a fish rescue and relocation effort where any remaining *O. mykiss* in the upstream pool in the North Channel would be captured and relocated prior to and during dewatering the pool. Habitat in the North Channel dewatering area was not designed as a part of FOCP to be suitable or preferred steelhead habitat, but instead the channel is designed to handle high flows in a manner that protects the South Channel and Live Oak Reach Restoration Project. Therefore, steelhead presence is not expected in the North Channel, but if present~~, the excluders and~~ rescue and relocation plan and use of exclusion devices will minimize impacts.

~~Once fish are excluded from the North Channel and the backwater pool is dewatered, the North Channel would be graded to connect the area where the existing backwater was located at the confluence of the North and South channels. Grading to create positive drainage toward the existing backwater and elimination of deep pools in the existing wetted channel is not anticipated to impact steelhead because they would have already been excluded from the work area and the area would be dewatered. The grading would ultimately benefit steelhead by decreasing stranding risk once the cofferdam is removed and the North Channel is activated again during high flow.~~

~~Construction~~ Maintenance activities would not impact water quality downstream of the work area because localized work areas within the ~~entire~~ North Channel would be dry prior to the start of ~~construction~~ maintenance activities or construction. BMPs GEN-26, GEN-31, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, and AMM-11, will minimize the pollution from vehicle fluids or other oily, greasy, or sediment-laden materials from entering the North Channel and washing downstream during high flows when the channel is activated by maintaining clean conditions at work sites, keeping spill kits available onsite to clean up any accidental spills, training personnel to properly use spill kits, fueling and cleaning vehicles and equipment off site, keeping vehicles maintained and clean, and inspecting vehicles and equipment daily for leaks prior to initiation of work.

~~The North Channel would be graded so that it extends through County Parks and private property to connect with the confluence of the North and South Channels of Coyote Creeks, where the existing North Channel currently forms a backwater. Currently the North Channel does not support topography that supports flows through this area. With positive drainage from the North Channel to the confluence, the restored North Channel would be designed to facilitate drainage. Grading would also channel flows towards the center of the North Channel so that flows would continue to the greatest extent feasible during low-flow times. This change in grading and flows would reduce fish stranding and stabilize both banks to protect Santa Clara County property. The north channel downstream of the north weir would be graded to reduce fish stranding when flows recede. This would include a slight slope towards the center of the channel and a slight, approximately 1 percent slope towards ADTP project limits (towards Coyote Creek). Upstream of the north weir, within a perennial backwater, a wetland bench would be installed to create suitable habitat for wetland vegetation. Riparian planting along some margins of the northern channel would be installed. The North Channel itself would not provide additional habitat for steelhead but reduces potential stranding and allow for restoration of the South Channel .~~

In the short term, impacts on steelhead would be less than significant. Over the long-term, steelhead would benefit from protection of South Channel habitat, reduced stranding and predation in the existing North Channel when they dewater following activation.

Maintenance of Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach

At the end of FOCP (existing conditions baseline), the Live Oak Restoration Reach project will have been completed providing new and enhanced spawning and rearing habitat for steelhead. The maintenance of the spawning gravel and the habitat improvements would continue as part of the Project. To maintain steelhead habitats, the extent of spawning gravels to replenish would be assessed during visual observations and following monitoring surveys. Inferential and calculated volumes for spawning gravel volumes would be used to evaluate the need for replenishment of spawning gravel volumes. Stockpiled spawning gravel would be added in small increments to maintain steelhead adult spawning habitat. Maintaining this habitat by continued placement of gravel has the potential to degrade water quality downstream of the work area if gravel and associated fine sediment enter the stream at the time of placement, which could impact rearing steelhead. However, gravels would be thoroughly washed of fine sediment prior to placement and silt curtains with a belting conveyor would be used to place the gravels, limiting impacts to aquatic and riparian areas. ~~gravel would not be placed directly in the channel, but would be placed adjacent to the channel or on benches above the channel so there would be no impact from introducing gravels to the channel at the time of placement. Also, when flows are high enough to mobilize the gravels in the gravel augmentation piles, there would already be elevated background levels of suspended sediment; therefore, additional sediment from the gravel piles would not add substantially to the total sediment that is already suspended during high flows.~~

Though it is not anticipated that ~~gravel and associated~~ fine sediment would enter the stream at the time of placement, measures would be implemented to protect steelhead in the unlikely event that this occurs. BMP BI-2 and GEN-1 restrict in-channel maintenance activities to the in-channel work window (June 15 to October 15). This work window minimizes impacts by minimizing chances of sedimentation and minimizes impacts to migrating steelhead because adults immigrate December through April and smolts outmigrate February through May. However, rearing juveniles occur in Coyote Creek year-round. BMPs GEN-16 and WQ-1 will minimize pollution entering the channel from construction equipment by constraining work activities to the top of bank if access is available and there are flows in the channel. BMPs GEN-26, GEN-31, GEN-32, WQ-11, HM-8, as well as AMM-7, AMM-8, and AMM-11, will minimize the pollution from vehicle fluids or other oily, greasy, or sediment-laden materials that could enter the creek from the work area by maintaining clean conditions at work sites, keeping spill kits available onsite to clean up any accidental spills, training personnel to properly use spill kits, fueling and cleaning vehicles and equipment off site, keeping vehicles maintained and clean, and inspecting vehicles and equipment daily for leaks prior to initiation of work.

Staging and stockpiling areas located immediately downstream of the dam could introduce sediment to the channel during precipitation events. Pollution could also be introduced from vehicles and equipment in staging and stockpiling areas. BMPs GEN-21 and WQ-4, as well as AMM-66, AMM-67, AMM-68, AMM-84, and AMM-97, will reduce sediment entering the channel from staging and stockpiling areas by covering sediment piles or surrounding with erosion control measures, filtering runoff, limiting the length of time materials can be stockpiled, and not placing sediment where it could spill into water bodies or storm drains. BMPs GEN-26, GEN-31, GEN-32, WQ-11, HM-8, as well as AMM-7, AMM-8, and AMM-11, will minimize the pollution entering the channel by maintaining clean conditions at staging and stockpiling areas, keeping spill kits available onsite to clean up any accidental spills and training personnel to properly use spill kits, cleaning vehicles and equipment offsite, keeping vehicles maintained and clean, inspecting vehicles and equipment daily for leaks prior to initiation of work, and utilizing secondary containments when fueling vehicles and equipment in staging and stockpiling areas.

Suspended sediment and turbidity impacts would be controlled by BMPs and mitigation measures and would be periodic ~~(during and after storm events)~~ and temporary lasting only during the construction phase. In the short term, impacts on steelhead would be less than significant. Over the long-term, steelhead would benefit from maintaining spawning habitat in the Live Oak Restoration reach that was enhanced during FOCP.

Sediment Augmentation Program

The Sediment Augmentation Program would improve geomorphic processes that create and maintain aquatic habitat for native species, including steelhead habitat. It would also reduce and reverse channel incision benefiting steelhead habitat in Coyote Creek. Sediment would be placed in the Live Oak Restoration Reach and/or Ogier Ponds Restoration Reach, beginning with the Live Oak Restoration Reach. Sediment would be placed on the benches ~~next to the~~ with the toe interacting with the channel in the CWMZ ~~and the Ogier Ponds CM restored channel~~ so that it would be mobilized during high-flow events. Placement of sediment has the potential to degrade water quality downstream of the work area if sediment enters the stream at the time of placement which could impact rearing steelhead. However, sediment would not be placed directly in the channel except for the toe of the sediment pile, the rest ~~but~~ would be placed adjacent to the channel or on benches above the channel so there would be minimal ~~no~~ impact from introducing sediment to the channel at the time of placement. Also, when flows are high enough to mobilize the sediment in the sediment augmentation piles there would already be elevated background levels of suspended sediment; therefore, additional sediment from the piles would not add substantially to the total sediment that is already suspended during high flows.

Though ~~it is not anticipated that~~ minimal sediment would enter the stream at the time of placement, measures would be implemented to protect steelhead ~~in the unlikely event that this occurs~~. BMPs BI-2 and GEN-1 restrict in-channel maintenance activities to the in-channel work window (June 15 to October 15). This work window minimizes impacts to all life stages by minimizing sedimentation and minimizes impacts to migrating steelhead because adults immigrate December through April and smolts outmigrate February through May. However, rearing juveniles occur in Coyote Creek year-round. BMPs GEN-16 and WQ-1 will minimize pollution entering the channel from construction equipment by constraining work activities to the top of bank if access is available and there are flows in the channel. BMPs GEN-26, GEN-31, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, and AMM-11, will minimize the pollution from vehicle fluids or other oily, greasy, or sediment-laden materials that could enter the creek from the work area by maintaining clean conditions at work sites, keeping spill kits available onsite to clean up any accidental spills, training personnel to properly use spill kits, fueling and cleaning vehicles and equipment off-site, keeping vehicles maintained and clean, and inspecting vehicles and equipment daily for leaks prior to initiation of work.

Suspended sediment and turbidity impacts have a low likelihood of occurring and would be temporary if they do occur. In the short term, impacts on steelhead would be less than significant. Over the long-term, steelhead would benefit from improved geomorphic processes that create and maintain spawning habitat and reduce and reverse channel incision.

Phase 2 Coyote Percolation Dam Fish Passage Enhancements

While the Phase 2 Coyote Percolation Dam CM would benefit steelhead once complete, construction activities to complete the Conservation Measure could have short-term impacts. Construction of this Conservation Measure requires localized dewatering. Localized dewatering during construction activities has the potential to strand steelhead or trap them in pools, subjecting them to increased predation pressure or water quality degradation. Construction activities also have the potential to degrade water quality downstream of the work area due to increased suspended sediment or other materials in the water.

Due to high water temperatures during the dry season work window and suboptimal habitat conditions, no steelhead are anticipated to be present in the Phase 2 Coyote Percolation Dam CM construction area during the period of disturbance. This portion of Coyote Creek is a migratory corridor and steelhead are likely only here seasonally. However, measures would be implemented to protect any steelhead that may be present. BMP BI-2 would protect steelhead from stranding during dewatering and impacts from increased suspended sediment in the channel by restricting in-channel construction activities to the dry season work window. This work window minimizes impacts to migrating steelhead because adults immigrate December through April and smolts outmigrate February through May. Though unlikely, if any rearing steelhead juveniles are present in the work area, they would be subject to stranding during dewatering. An agency-approved aquatic species rescue and relocation plan for the Phase 2 Coyote Percolation Dam CM would reduce impacts of fish stranding during localized dewatering by implementing a fish rescue and relocation effort during localized dewatering, whereby *O. mykiss* would be excluded from the work area with block nets and/or captured and relocated prior to and during dewatering. Capture methods would include backpack electrofishing, seining, dip netting and/or capturing by hand. Impacts would include stunning, netting, capturing, and handling causing acute physiological stress. Injury or mortality can happen occasionally but are rare. Most steelhead tolerate capture and handling.

Implementation of BMPs GEN-35, WQ-3, and AMM-17 will protect steelhead from being injured or killed during dewatering activities or pumping streamflow around the work site by using pumps and intake hoses screened according to NMFS and CDFW criteria to prevent uptake of fish and other vertebrates. AMM-91 and CDFW authorization for sacrifice of non-native species could reduce predation pressure and/or competition from nonnative fish, crayfish, American bullfrogs, and red-eared sliders at least in the short-term (long term benefits are less likely unless eradication is achieved). BMP BI-11 and AMM-90 will minimize attracting predators to the work site by requiring that trash be removed daily from the construction area.

BMPs GEN-20 and WQ-16, as well as AMM-66, AMM-84, and AMM-97, will reduce sediment entering the channel from the work area during precipitation events by installing erosion control measures (e.g., silt fences, straw bales, etc.) and visually inspecting erosion control measures during and following extended storm events. BMPs GEN-26, GEN-31, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, and AMM-11, will minimize the pollution from vehicle fluids or other oily, greasy, or sediment-laden materials that could enter the creek from the work area by maintaining clean conditions at work sites, keeping spill kits available onsite to clean up any accidental spills and training personnel to properly use spill kits, fueling and cleaning vehicles and equipment off-site, keeping vehicles maintained and clean, and inspecting vehicles and equipment daily for leaks prior to initiation of work. BMP WQ-15 would protect steelhead downstream of the work area from impacts of degraded water quality by keeping any oily, greasy, or sediment-laden substances away from places they may enter the waterway and monitoring water turbidity changes downstream of the work area and any discharge points.

The Phase 2 Coyote Percolation Dam CM would build upon the Phase 1 design from FOCP to improve upstream and downstream passage at the Coyote Percolation Dam area. Phase 1 improvements are part of the existing conditions baseline and they include 1) replacing the existing steel flashboard dam with an inflatable bladder dam, 2) constructing a portion of a roughened channel to provide upstream and downstream fish passage routes over the dam when the bladder dam is deflated (i.e., Dam-Down conditions), 3) upgrading the approach channel to the fish ladder to a roughened channel that better meets fish passage hydraulic criteria, and 4) upgrading portions of the fish ladder to meet fish passage hydraulic criteria over an increased range of flows. Phase 2 would build on these improvements to meet the most recent applicable ~~CDFW (Love and Bates 2009) and~~ NMFS (NMFS 2023 ~~2022~~) and CDFW (Love and Bates 2009) design criteria for anadromous fish passage across the entire range of design flows. Phase 2 improvements will include 1) constructing a roughened channel ~~over~~ downstream of the dam to provide improved upstream and downstream fish passage over the deflated bladder dam at higher flows, 2) replacing ~~the~~ one of the two radial gates next to the fish ladder with an overshot ~~bypass~~ weir~~s~~ to provide more suitable conditions for both up and downstream passage at lower flows, and 3) other facility modifications to meet the most recent applicable ~~CDFW (Love and Bates 2009) and~~ NMFS (2023 ~~2022~~) and CDFW (Love and Bates 2009) fish passage design criteria~~, including~~. In addition, studies will be conducted on juvenile fish passage and predation risks through the pond complex post-enhancements to assess if additional changes are necessary to improve juvenile out-migration. Therefore, the updated Coyote Percolation Dam after the completion of Phase 2 will allow fish passage at a wider range of flows, including across all CDFW (Love and Bates 2009) and NMFS (2023 ~~2022~~) design flows, with less delay and safer downstream passage.

Overall, short-term construction related impacts would be less than significant, and in the long term the Phase 2 Coyote Percolation Dam CM would benefit steelhead migration facilitating anadromous production of the population in the watershed.

Construction Monitoring

Construction Phase Fisheries Monitoring

Fisheries monitoring will provide valuable information to inform management of steelhead in the study area both during and after completion of construction and guide Valley Water and regulatory agencies in decision-making regarding the Fish Rescue and Relocation Plan, the Sediment Augmentation Program and other habitat restoration efforts. Water ~~temperature~~ quality monitoring, suspended sediment monitoring, sediment deposition monitoring, VAKI Riverwatcher adult escapement monitoring, spawning surveys, eDNA, migration flow monitoring, ~~and~~ non-native control methods, reptile monitoring, and terrestrial animal monitoring would have no impacts on steelhead. Sensitive Habitat Monitoring and Groundwater Monitoring would not adversely impact steelhead as these studies do not require in-channel sampling. Groundwater monitoring would not adversely impact steelhead, because monitoring wells are located outside the active channel of Coyote Creek. ~~Therefore, there is no impact.~~

There will be some impacts from juvenile rearing studies, PIT tag migration study, and growth comparative study. Stunning/netting, capturing, handling, and tagging would cause acute physiological stress. Injury and mortality are rare but happen occasionally. Valley Water would be subject to the terms and conditions of their ESA 10(a)1(A) recovery permit and CDFW Scientific Collecting Permits which include impact avoidance and minimization measures during these studies.

Construction Phase Fish Rescue and Relocation; Juvenile Rearing, Migration, and Growth

If monitoring of water temperature and DO indicates that conditions for rearing steelhead would become unsuitable within the Coyote Creek FCWMZ as a result of Seismic Retrofit construction activities, steelhead would be rescued and relocated per the Fish Rescue and Relocation Plan. In addition. Localized dewatering plans when developed may require preparation of localized dewatering plans under BMP BI-2. For both types of plans, capture methods would include backpack electrofishing and/or seining. Steelhead would be stunned/netted, captured, and handled causing acute physiological stress. Injury or mortality can happen occasionally but are rare. Most steelhead tolerate capture and handling. Acute physiological stress would be temporary and less of an impact than mortality under deteriorating water quality conditions.

Valley Water has also documented steelhead successfully rearing through the summer despite times of temperatures increasing above optimal range. This information gathered prior to the Project will be used in technical working group discussions to balance the risks of capture and relocation with the risks of allowing steelhead to remain in the FCWMZ under suboptimal conditions, therefore the Fish Rescue and Relocation Plan and fish relocation efforts under BMP BM-1 plans would have less than significant impacts on steelhead.

Invasive Species Monitoring and Control Plan

The Invasive Species Monitoring and Control Plan is outlined in Section 2.7.6.2 and was prepared for the FOCP and would continue to be implemented through construction of the Project. The species targeted by the plan include non-native fish, crayfish, American bullfrog, and red-eared slider, as well as opportunistic removal of other non-native species. The decontamination protocols and signage discouraging release of unwanted pets would have no adverse impacts on steelhead and the prevention of spreading diseases and pathogens would help minimize impacts to steelhead from the Project. The Invasive Species Monitoring and Control Plan also implements the opportunistic capture and dispatch of non-native species when they are encountered during monitoring activities or during implementation of individual aquatic species rescue and relocation plans during local dewatering for construction activities or the Fish Rescue and Relocation Plan in the FCWMZ. Because capture and dispatch would be opportunistic and conducted during other construction activities and monitoring, including during fish rescue and relocation, already assessed for steelhead impacts, there would be no additional impacts on steelhead not already considered, and steelhead may benefit in the longer term in locations where invasive species are removed, particularly piscivorous (fish-eating) fish, crayfish, and bullfrogs. However, benefits would likely be temporary because systematic eradication of non-native species entirely is not feasible, so such species are likely to reinvade areas where some were removed.

Construction Monitoring Summary

Overall, construction monitoring would result in less-than-significant impacts to steelhead in the short-term and would benefit steelhead in the long-term.

Post-Construction Seismic Retrofit and Instream Flows Operations (FAHCE Rule Curves)

This section analyzes the impacts and benefits of implementing the FAHCE rule curves (i.e., the Project) compared with Pre-FERC Order Baseline Conditions, and Future Baseline conditions based on results of WEAP modeling and project design objectives for non-flow restoration actions. In addition, the WEAP Model results for steelhead fry and juvenile habitat are compared with the HCM results to provide a more detailed assessment of habitat for these steelhead life stages in the FCWMZ under Pre-FERC Order Baseline Conditions. Benefits of the Conservation Measures, including maintenance of the Live Oak Restoration Project; construction, operations, and maintenance of the North Channel Reach ~~Extension~~, Coyote Percolation Pond Phase 2 design improvements, Sediment Augmentation Program, and Ogier Ponds CM are also qualitatively considered in the analysis but are not included in the WEAP Model results. This section provides the relevant summaries of modeled changes in habitat from the WEAP Model outputs which are provided with more detailed technical methods in Appendix F, Biological Resources – Fisheries ~~Resources~~ Technical Appendix.

Spawning and Incubation Habitat

The Project is predicted to result in an increase in steelhead spawning and incubation habitat compared with the Future Baseline, with a predicted decrease in spawning and incubation habitat relative to the Pre-FERC Order Baseline. The analysis of these changes is nuanced and complex, with relevant summaries presented here and full analysis in Appendix F.

The WEAP Model predicts 21,876 square feet of incubation adjusted steelhead spawning habitat in Coyote Creek under the Project. Approximately 8,000 square feet of the spawning habitat would occur in the FCWMZ and just over 13,800 square feet would occur in reaches downstream of the FCWMZ. Compared with the Pre-FERC Order Baseline, the WEAP Model predicts a decrease in spawning habitat in the FCWMZ and an increase in reaches downstream of the FCWMZ, with an overall decrease of 1,500 square feet (6.4 percent) under the Project, due not just to implementation of FAHCE rule curve releases and operations as a result of the Project, but also do to differing assumptions in the WEAP model about factors like Pre-FERC Order water supply releases and water demand that vary from existing conditions for reasons unrelated to the Project. Compared with the Future Baseline, the Project would increase incubation adjusted steelhead spawning habitat in Coyote Creek. Increases relative to the Future Baseline would occur in the FCWMZ and in downstream reaches, with an overall increase of 3,900 square feet (21.7 percent). Comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order Baseline because both the Project and Future Baseline scenarios represent conditions occurring at the same point in time (i.e., 2035) and both are based on the same assumptions regarding water conservation, water supply and demand, climate change, and other factors affecting flows and habitat in Coyote Creek (see Chapter 5.0, *Alternatives*, for discussion of No Project Alternative). Accordingly, the Project would benefit spawning and incubation habitat in the long term, and therefore spawning steelhead.

Comparison of the WEAP Model predictions under the Pre-FERC Order Baseline and the Future Baseline indicates that, without the Project, spawning habitat is predicted to decrease in Coyote Creek downstream of Anderson Dam as a result of factors other than the Project. Under Pre-FERC Order Baseline Conditions, the WEAP model predicts an average total of 23,407 square feet of incubation adjusted steelhead spawning habitat in Coyote Creek downstream of the dam. Under Future Baseline conditions, the WEAP model predicts a total of 17,952 square feet of incubation adjusted steelhead spawning habitat downstream of the dam. This represents a predicted decrease in spawning habitat of 5,455 square feet under the Future Baseline, regardless of Project implementation, as compared with Pre-FERC Order Baseline. This decrease is based on factors that are not related to implementation of the Project or its FAHCE rule curves (~~-~~e.g., changes in conservation, water supply demand resulting in less imported water released into Coyote Creek), and this decrease is predicted to occur without implementation of the Project. In other words, the Project would reduce the loss of steelhead spawning habitat that is otherwise predicted to occur between Pre-FERC Order Baseline and Future Baseline conditions. As described above, the Project would also result in a net benefit to spawning habitat compared with the conditions that would occur without the Project (i.e., Future Baseline conditions).

In addition to the WEAP Model habitat predictions and reductions in releases to Coyote Creek expected to occur in the absence of the Project, evaluation of Project effects on spawning and incubation habitat must take into account the implementation of several spawning habitat restoration Conservation Measures. The Ogier Ponds CM Project is estimated to add over 20,000 square feet of spawning habitat at typical winter baseflow (approximately 30 cfs). The additional spawning habitat created by the Ogier Ponds CM would be maintained and supplemented by Project maintenance of spawning habitat improvements added to the Live Oak Reach, and the Sediment Augmentation Program, which will rely on placement of bed materials to improve spawning substrate on benches within the CWMZ and then increased flow conveyance from the North Channel Extension, constructed as part of FOCP, ~~Project~~ to distribute those materials. These Conservation Measures would contribute to substantial additional increases in spawning habitat and steelhead production potential in Coyote Creek downstream of Anderson Dam, which will be maintained in perpetuity as a part of ongoing operations.

Furthermore, implementation of the Ogier Ponds CM would improve spawning suitability downstream of Ogier Ponds by disconnecting the creek from the ponds and eliminating the introduction of warmed water from the ponds to Coyote Creek, thereby reducing water temperatures and improving habitat suitability in the restored creek channel downstream of Ogier Ponds during warmer months (Valley Water 2023b ~~2023c~~). The WEAP Model results indicate that water temperatures under the Pre-FERC Order Baseline are sufficiently elevated to limit successful steelhead incubation downstream of Ogier Ponds. Therefore, implementation of the FAHCE rule curves in combination with the construction, operation, and maintenance of Ogier Ponds CM, the maintenance of spawning habitat created by FOCP in the Live Oak Restoration Reach, and implementation of the Sediment Augmentation Program combined with increased flow conveyance through the North Channel Extension (constructed as part of FOCP) would contribute to additional increases in steelhead production potential in Coyote Creek downstream of Anderson Dam.

Overall, the amount of spawning and incubation habitat under the Project would increase substantially relative to the Future Baseline with implementation of the FAHCE rule curves and the habitat restoration Conservation Measures with overall benefits to steelhead. Also, the continued Maintenance of the Spawning Habitat Improvements in the Live Oak Restoration Reach would maintain spawning habitat through the Project that was improved during FOCP <u>and enhanced protection from higher flows from the North Channel Extension</u> (see Section 3.4.5. *Cumulative Impacts*) ~~and the North Channel Extension will aid this maintenance by sending high flows down the north channel, protecting the south channel improvements in the Live Oak Restoration Reach.~~

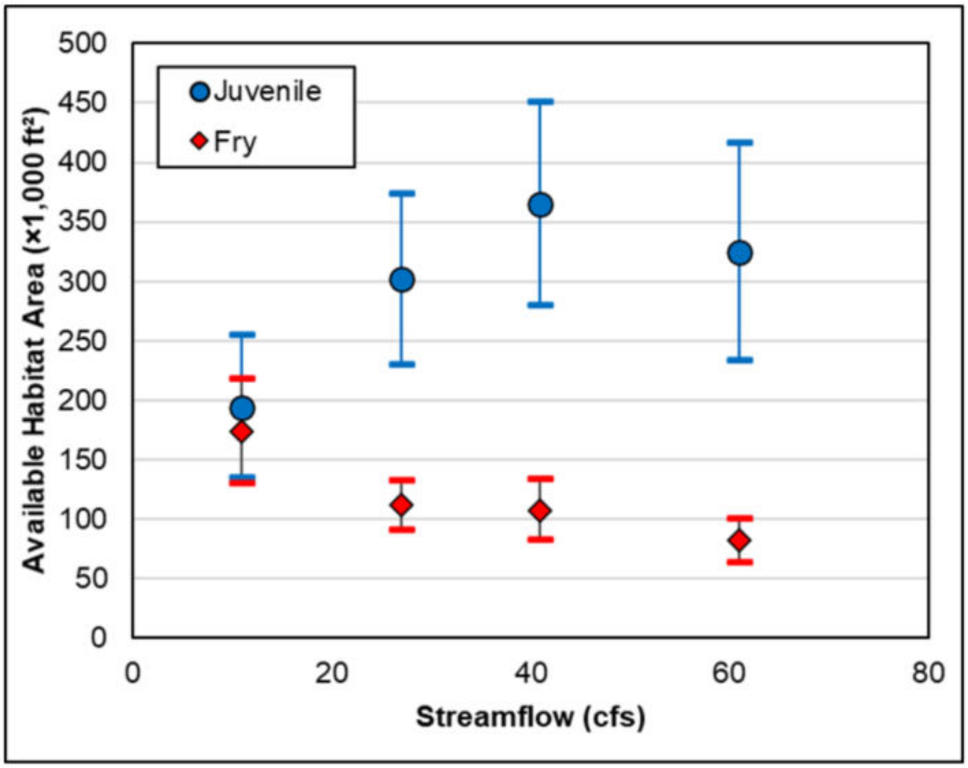
Fry Rearing Habitat

Implementation of the FAHCE rule curves under the Project is predicted to decrease fry rearing habitat compared with both the Pre-FERC Order Baseline and the Future Baseline. The analysis of these changes is nuanced and complex, with relevant summaries presented here.

The WEAP Model predicts 2,206,220 square feet of steelhead fry rearing habitat in Coyote Creek under the Project. Approximately 216,000 square feet of the fry rearing habitat would occur in the FCWMZ and approximately 1,990,000 square feet would occur in reaches downstream of the FCWMZ. Compared with the Pre-FERC Order baseline, the WEAP Model predicts a 4.1 percent increase in fry rearing habitat in the FCWMZ and a 1.7 percent decrease in reaches downstream of the FCWMZ, with an overall decrease of 25,700 square feet (1.2 percent) under the Project. Compared with the Future Baseline the Project is predicted to result in similar, but smaller, changes in predicted fry rearing habitat. Under the Project, the WEAP Model predicts a 3.8 percent increase in steelhead fry rearing habitat in the FCWMZ, a very small (0.6 percent) decrease in reaches downstream of the FCWMZ, and an overall decrease of 3,400 square feet (0.2 percent) compared with the Future Baseline. Comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order baseline because both the Project and Future Baseline scenarios represent conditions occurring at the same point in time (i.e., 2035) and both are based on the same assumptions regarding water supply and demand, climate change, and other factors affecting flows and habitat in Coyote Creek (see Chapter 5, *Alternatives*). Accordingly, effects of the Project on fry rearing habitat are evaluated primarily by comparison with the Future Baseline.

While the decreases in habitat downstream of the FCWMZ are due to both changes in flow and water temperature under the Project, the modeled decreases downstream of the FCWMZ are typically the result of flow variations, and notably do not consider the substantial benefits of the construction, operation, and maintenance of the Ogier Pond CM and the continued maintenance of the Rearing Habitat Improvements in Live Oak Restoration Reach. Decreases are most often due to lower flows (mostly in the month of May when flows are reduced for cold water management) that reduce the wetted area in the channel available for fry rearing habitat. Occasionally decreases in fry habitat occur due to higher flows under the Project that reduce the water velocity suitability for fry rearing or slight increases in water temperature. As illustrated by the HCM estimates, which are based on field mapping of fry rearing habitat under Pre-FERC Order Baseline Conditions at different flows (**Figure 3.4-3**), fry rearing habitat was found to decrease with increasing flow due to increasing water velocities that become unsuitable for fry rearing within portions of the channel (Stillwater Sciences 2021). Pulse flows prescribed by the Project may result in velocities that reduce the water velocity suitability for steelhead fry.

Figure 3.4-3. Habitat Criteria Mapping estimates of available habitat area for steelhead fry and juvenile rearing life stages under the Pre-FERC Order Baseline in the Functional Cold Water Management Zone at various streamflows measured at the Madrone Gage 5082 (Stillwater Sciences 2021). Vertical bars represent 95 percent confidence intervals.



These WEAP model habitat predictions do not take into account fry rearing habitat created by the Conservation Measures, the Ogier Ponds CM (which is part of the Project) is estimated to add over 33,000 square feet of shallow water habitat for fry rearing in inundated margin habitat at a range of ~~typical~~ spring and summer flows (approximately 30-50 cfs). Implementation of the Ogier Ponds CM would improve fry rearing suitability downstream of Ogier Ponds by disconnecting the creek from the ponds and eliminating the introduction of warmed water from the ponds to Coyote Creek, thereby reducing water temperatures in the restored creek channel as well as the channel downstream of Ogier Ponds during warmer months (Valley Water 2023b ~~2023c~~). The WEAP Model results indicate that water temperatures under the Pre-FERC Order Baseline are occasionally elevated sufficiently to limit steelhead fry rearing downstream of Ogier Ponds. Therefore, implementation of the FAHCE rule curves in combination with the Ogier Ponds CM would contribute to additional increases in steelhead production potential in Coyote Creek downstream of Anderson Dam.

Although the modeled amount of total fry rearing habitat would be lower under the Project than under Future Baseline conditions and Pre-FERC Order Baseline Conditions, reductions in fry habitat would occur only in reaches downstream of the FCWMZ and would be negligible (less than 1 percent compared with the Future Baseline). Considering the abundance of fry rearing habitat downstream of the FCWMZ (more than 2 million square feet), the small reductions predicted under the Project are not expected to adversely affect steelhead production potential.

Furthermore, implementation of the FAHCE rule curves under the Project would increase fry rearing habitat in the FCWMZ compared to Pre-FERC Order and Future Baseline where temperatures are managed to benefit steelhead. With construction, operation, and maintenance of the Ogier Ponds CM, the modeled decrease in fry rearing habitat downstream of the FCWMZ would be offset by the increased fry rearing habitat created in the Ogier Ponds restoration area and the temperature-related improvements in fry rearing habitat suitability downstream of Ogier Ponds. The combined results of implementing the FAHCE rule curves and the Ogier Ponds CM and the Sediment Augmentation Program would provide overall benefits to steelhead fry rearing and ~~potentially~~ increase steelhead production potential in Coyote Creek downstream of Anderson Dam. Also, the continued Maintenance of the Rearing Habitat Improvements in the Live Oak Restoration Reach would maintain fry rearing habitat through the Project that was improved during FOCP (see Section 3.4.5, *Cumulative Impacts*). ~~Changes to~~ Maintenance of the conveyance and flow splits between the north and the south channel from the Maintenance of the North Channel Reach ~~Extension~~ would aid the maintenance of rearing habitat in the south channel from the Live Oak Restoration Project.

Juvenile Rearing Habitat

The Project is predicted to result in an increase in steelhead juvenile rearing habitat compared with the Future Baseline, with a predicted decrease in juvenile rearing habitat relative to the Pre-FERC Order Baseline.

The WEAP Model predicts 2,574,967 square feet of steelhead juvenile rearing habitat in Coyote Creek under the Project. Approximately 276,900 square feet of the fry rearing habitat would occur in the FCWMZ and approximately 2,298,000 square feet would occur in reaches downstream of the FCWMZ. Compared with the Pre-FERC Order Baseline, the WEAP Model predicts a 4.5 percent decrease in juvenile rearing habitat in the FCWMZ and an 8 percent decrease in reaches downstream of the FCWMZ, with an overall decrease of 212,000 square feet (7.6 percent) under the Project. The amount of juvenile rearing habitat under Pre-FERC Order Baseline Conditions in the FCWMZ predicted by the WEAP model (289,739 square feet) falls within the range of juvenile rearing habitat estimated by the HCM study at a flow of 27 cfs (**Figure 3.4-3**). Because HCM-derived estimates of juvenile rearing habitat in the FCWMZ at flows of 27, 41, and 60 cfs do not differ significantly, the consistency between the WEAP model predictions and the range of HCM estimates at 27 cfs suggests that the WEAP model results are a reasonably accurate prediction of juvenile habitat availability. Compared with the Future Baseline, the Project would increase steelhead juvenile rearing habitat in Coyote Creek. Increases relative to the Future Baseline would occur in the FCWMZ and in downstream reaches, with an overall increase of 32,300 square feet (1.3 percent). As described previously, comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order Baseline. Accordingly, the Project would benefit rearing juvenile steelhead.

Comparison of the WEAP Model predictions under the Pre-FERC Order Baseline and the Future Baseline indicates that, without the Project, juvenile rearing habitat is predicted to decrease in Coyote Creek downstream of Anderson Dam. Under Pre-FERC Order Baseline Conditions, the WEAP model predicts an average total of 2,786,971 square feet of steelhead juvenile rearing habitat in Coyote Creek downstream of the dam. Under Future Baseline conditions, the WEAP model predicts a total of 2,542,715 square feet of steelhead juvenile rearing habitat downstream of the dam. This represents a predicted decrease in juvenile rearing habitat of

244,256 square feet under the Future Baseline compared with Pre-FERC Order Baseline, with modeled decreases in baseline juvenile rearing habitat of 40,945 square feet in the FCWMZ and 203,311 square feet downstream of the FCWMZ (including Ogier Ponds). This decrease is based on factors that are not related to implementation of the Project or its FAHCE rule curves (e.g., changes in conservation, water supply demand resulting in less imported water released into Coyote Creek), Since this decrease is predicted to occur without implementation of the Project, the Project would reduce the loss of steelhead juvenile rearing habitat that is otherwise predicted to occur between Pre-FERC Order Baseline and Future Baseline conditions. As described above, the Project would also result in a net benefit to juvenile rearing habitat compared with the conditions that would occur without the Project (i.e., Future Baseline conditions).

The WEAP Model habitat predictions do not reflect habitat restoration Conservation Measures such as the Live Oak Restoration and Ogier Ponds Project. The Ogier Ponds CM alone is estimated to restore over 67,000 square feet of additional juvenile rearing habitat at a range of ~~typical~~ spring and summer flows (approximately 30-50 cfs) (Valley Water and Stillwater Sciences 2024). Implementation of the Ogier Ponds CM would improve juvenile rearing suitability downstream of Ogier Ponds by disconnecting the creek from the ponds and eliminating the introduction of warmed water from the ponds to Coyote Creek, thereby reducing water temperatures in the restored creek channel and the channel downstream of Ogier Ponds during warmer months (Valley Water 2023b ~~2023c~~). The WEAP Model results indicate that water temperatures under the Pre-FERC Order Baseline are occasionally elevated sufficiently to limit steelhead juvenile rearing downstream of Ogier Ponds. Therefore, implementation of the FAHCE rule curves in combination with the Ogier Ponds CM would contribute to additional increases in steelhead production potential in Coyote Creek downstream of Anderson Dam.

Although the modeled amount of total juvenile rearing habitat would be lower under the Project than under Pre-FERC Order Baseline Conditions, the Project would provide more juvenile rearing habitat compared with the Future Baseline, with most of the increase in the CWMZ where temperatures are more easily managed. As described previously, comparisons between the Project and the Future Baseline provide a more accurate depiction of project benefits. With construction, operation, and maintenance of the Ogier Ponds CM, the increased juvenile rearing habitat created in the Ogier Ponds restoration area and the temperature-related improvements in juvenile rearing habitat suitability downstream of Ogier Ponds would provide overall benefits to steelhead juvenile rearing in Coyote Creek downstream of Anderson Dam. Also, the continued Maintenance of the Rearing Habitat Improvements in the Live Oak Restoration Reach and the Sediment Augmentation Program ~~sediment augmentation program~~ would maintain juvenile rearing habitat through the Project that was improved during FOCP (see Section 3.4.5, *Cumulative Impacts*).

Adult Upstream Passage

The WEAP Model results indicate that flows in Coyote Creek under the Project would provide increased opportunities for upstream migration of adult steelhead compared with both baseline scenarios. The increased upstream migration opportunities would result mostly from increased frequency and duration of flow releases from Anderson Dam during the steelhead migration season. Compared with the Pre-FERC Order Baseline, flows under the Project would increase the average and maximum number of days in which conditions during the annual December–April adult migration period would be suitable for upstream passage into the FCWMZ (i.e., upstream of POI COYO 9), which is the location where suitable steelhead spawning and incubation habitat is most consistently available. Suitable conditions for adult upstream migration would also be suitable for kelts (post-spawning adults returning to the ocean) migrating downstream after spawning. The increase in the average and maximum numbers of annual upstream passage days results from simulated increases in depth at critical riffles associated with increased pulse flow releases, reduced water temperature, or both. The *minimum* annual number of suitable passage days under the Project would decrease slightly (by 1 day) at POIs COYO 6–9 compared with the Pre-FERC Order Baseline. However, this negligible reduction is predicted to occur in only one of 20 years evaluated by the WEAP model, during which predicted migration opportunities at locations downstream of POIs COYO 6–9 are also few (i.e., 1 suitable passage day). It should be noted that the WEAP model assumes passage is only available if all POIs have suitable conditions for downstream passage, thus representing a conservative estimate (i.e., likely underestimate) of the opportunities that are available.

Compared with the Future Baseline, the WEAP Model results indicate that flows under the Project would increase the average and maximum number of days in which conditions during the annual December–April adult migration period would be suitable for upstream passage at all POIs. There would be no change in the minimum annual number of suitable upstream passage days at any location under the Project. As described previously, comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order Baseline. Accordingly, the Project would benefit migrating adult steelhead.

Conservation Measures would provide additional improvements in passage suitability for both adult and juvenile steelhead that are not accounted for by the WEAP Model results. Completion of the Ogier Ponds CM would provide additional passage improvements for adult steelhead by disconnecting Coyote Creek from the ponds, reducing pond entrainment and predation risk, reducing instream water temperature, and improving channel conditions in the restoration area. The Phase 2 Coyote Percolation Dam also improves migration conditions but passage at that location is already assumed in the WEAP Model.

For the reasons outlined above, the Project would benefit migrating adult steelhead, likely facilitating increased reproduction and an increased contribution of the anadromous life history type to the *O. mykiss* population in the watershed.

Juvenile Downstream Passage

The WEAP Model results indicate that flows in Coyote Creek under the Project would reduce opportunities for downstream migration of juvenile steelhead compared with the Pre-FERC Order Baseline but increase juvenile migration opportunities compared with the Future Baseline. Compared with the Pre-FERC Order Baseline, flows under the Project would reduce the median [9] number of days by 3 (30 percent) and also reduce the maximum number of days by 3 (8 percent) in which conditions during the annual February–May juvenile migration period would be suitable for downstream passage. The minimum annual number of suitable days for downstream passage would be zero under both the Project and the Pre-FERC Order Baseline. It should be noted that the WEAP model assumes passage is only available if all POIs have suitable

[9] For the downstream passage analysis, the median is presented instead of the average because the median better represents the central tendency when the data include multiple zero values (years with zero passage days), as is the case with the WEAP Model results for these two model scenarios.

conditions for downstream passage, thus representing a conservative estimate (i.e., likely underestimate) of the opportunities that are available.

Compared with the Future Baseline; however, flows under the Project would increase the median number of days by 5 (250 percent) and there would be no change in the maximum (34) or minimum (0) number of days in which conditions during the juvenile migration period would be suitable for downstream passage. As described previously, comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order Baseline. Accordingly, the Project would provide substantial benefits to outmigrating juvenile steelhead.

Ogier Ponds CM would provide additional improvements in passage suitability for outmigrating juvenile steelhead that are not accounted for by the WEAP Model results. Completion of the Ogier Ponds CM would improve migration conditions by disconnecting Coyote Creek from the ponds, reducing pond entrainment and predation risk, reducing instream water temperature, and improving channel conditions in the restoration area. The Phase 2 Coyote Percolation Dam also improves migration conditions but passage at that location is already assumed in the WEAP Model. Overall, post-construction instream flows and Conservation Measures that improve migration conditions would benefit downstream migrating juveniles.

Post-Construction Seismic Retrofit and Instream Flow Operations (FAHCE Rule Curves) Summary

Compared with the Future Baseline, the post-construction instream flows under the Project would have little or no adverse impacts on the steelhead population in Coyote Creek, with likely benefits to production and a potential increase in the contribution of anadromous individuals to the population. Compared with the Pre-FERC Order Baseline, the Project would slightly reduce habitat for some steelhead life stages, but, as previously described, comparisons with the Pre-FERC Order Baseline do not represent project impacts as accurately as comparisons with the Future Baseline. Overall, implementation of the FAHCE rule curves in combination with the habitat improvements from the Ogier Ponds CM, the Sediment Augmentation Program and continued maintenance of the Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach and ~~, combined with the~~ maintained conveyance improvements of the North Channel Reach ~~Extension and~~ as well as the migration benefits provided by Ogier Ponds CM creek separation and Phase 2 Coyote Percolation Dam CM, would benefit steelhead in Coyote Creek.

Post-Construction Seismic Retrofit Maintenance and Conservation Measures Operations, Maintenance, and Adaptive Management

Following Seismic Retrofit construction, the reservoir would be operated consistent with the FAHCE rule curves as discussed in the prior section *Post-Construction Seismic Retrofit and Instream Flows Operations* (FAHCE rule curves) and is not repeated here. This section addresses post-construction maintenance of Seismic Retrofit facilities, post-construction maintenance of Conservation Measures, and post-construction operations that involve actual conveyance of water through the Conservation Measure infrastructure components and restored habitat areas, as well as post-construction monitoring.

Anderson Dam Post-Construction Operations, Maintenance, and Monitoring

Once the Seismic Retrofit is complete, the reservoir would refill over a period of 1 to 2 years to the new maximum elevation. The new low-level and high-level outlets would allow more operational flexibility. This operational flexibility would benefit steelhead by allowing Valley Water to draw water from different levels in the reservoir to meet FAHCE temperature requirements for instream flows downstream of the dam.

All monitoring and maintenance of the dam and associated appurtenances would be covered under the DMP, SMP and the PMP, which have their own CEQA documents, and considering the extensive BMPs and mitigation measures like gravel augmentation and large wood placement for these programs, the monitoring and maintenance would have short-term less than significant impacts on and long-term benefits for the steelhead population.

Ogier Ponds CM Project Operations, Maintenance, and Monitoring

Monitoring of Ogier Ponds CM would be conducted annually for 10 years at design flows to determine the success of the project at achieving the restoration objectives, and to inform maintenance. Monitoring for suitable fry, juvenile, and spawning habitat would be mapped on the base map of the reach, based on accepted habitat suitability criteria (Stillwater Sciences 2021). Results would be used to inform maintenance of the project.

The restored channel created via the Ogier Ponds Conservation Measure will operate and function as a natural creek channel. There will be no management of flows or manipulation of features as a result of operations. Weirs will be activated infrequently when flow levels reach 2000 cfs, and will be spillover, not requiring any actions. Due to the infrequent nature of activation of the spillover weirs, impacts associated with potential entrainment would not cause a reduction in overall production in the species .Overall, the creek-lake separation at Ogier Ponds and channel restoration would provide many long-term benefits to steelhead and their critical habitat through increased and improved rearing habitat, enhanced migration conditions, decreased predation pressure, decreased water temperatures, and decreased competition. Combined, these improvements would support a larger and more resilient steelhead population in the watershed.

Following the disconnection of Coyote Creek from Ogier Ponds, maintenance may be required to maintain creek channel flow capacity, pond/creek separation, and low flow through the system of ponds as described in Section 2.9.2 ~~2.8.2~~ *Ogier Ponds Operations and Maintenance*. As discussed In Section 2.9.2, *Ogier Ponds Operations and Maintenance*, maintenance would include vegetation management and replanting or other efforts to establish native vegetation throughout the project footprint~~-~~. Berms, spillways, fish screens, in-channel bio-engineered habitat enhancements, rock slope protection, and stormwater outfalls would be inspected and repaired, as necessary. Additional maintenance activities would include trash removal, inspection and graffiti abatement at floodwalls, access road inspections, and road maintenance. Monitoring and maintenance of the newly restored channel would be covered under the SMP and its EIR. C~~but c~~onsidering the extensive BMPs and mitigation measures ~~(~~for this program, the monitoring and maintenance would have short-term less than significant impacts on long term benefits to the steelhead population.

North Channel Reach ~~Extension~~ Operations, Maintenance, and Monitoring

~~The North Channel would be activated (operated) during high flows, when outlet releases exceed 228 cfs. Conveyance of higher flows downstream through the North Channel would support more direct release of geomorphic restoration flows to Coyote Creek, which would enhance steelhead critical habitat, while protecting habitat in the South Channel and Live Oak Restoration Reach. Extension of the channel to improve drainage in the North Channel would decrease stranding risk when the channel flows dissipate. Since the North Channel did not have an upstream connection Pre-FERC Order conditions no comparison can be made to this baseline condition. For f these reasons, the construction of the North Channel Extension and post-construction North Channel Extension operations would benefit Steelhead.~~

As described in Section 2.9.3, *North Channel Reach ~~Extension Maintenance~~,* the North Channel would be monitored to ensure that the area is maintaining sufficient slope and grade to provide positive drainage. Maintenance would include debris and/or vegetation removal from the channel and bed stabilization. These activities may require localized ~~the~~ dewatering, minor grading and potential use of stabilization material within the channel bottom and banks. Long-term maintenance of the North Channel would protect the steelhead habitat features in the South Channel constructed during FOCP by passing high flows through the North Channel. Monitoring and maintenance of the North Channel ~~Extension~~ would be covered under the SMP and its EIR but considering the extensive BMPs and mitigation measures for this program, the monitoring and maintenance would have short-term less than significant impacts on and long-term benefits ~~impacts~~ to the steelhead population.

Monitoring and Maintenance of Spawning Gravel and Rearing Habitat Enhancements in the Live Oak Restoration Reach ~~and Sediment Augmentation Program~~

Live Oak Restoration Reach spawning gravel and rearing habitat enhancements ~~and the Sediment Augmentation Program e~~ would work in conjunction with the Sediment Augmentation Program (see below) to improve spawning substrate and geomorphic processes within the CWMZ and reduce and reverse channel incision, benefiting steelhead and their critical habitat. Maintenance of these habitat enhancements ~~Combined, these improvements~~ would support a larger and more resilient steelhead population in the watershed.

Valley Water would inspect ~~sediment and~~ habitat features and gravel augmentation sites within the Live Oak Restoration Reach ~~CWMZ, with particular but not exclusive focus on the Live Oak Restoration Reach and the Ogier Ponds creek channel area,~~ to determine if habitat features and spawning substrate maintenance is required to address erosion, destabilization, and/or mobilization of habitat features and channel incision or fine sedimentation following large flow events. Maintenance would include placing 5 to 500 cubic yards of spawning gravels ~~or coarse sediments~~ within ~~Coyote Creek~~ the Live Oak Restoration Reach. Spawning gravels would be placed in the channel using sediment curtains and a belting conveyor. Alternatively, the Sediment Augmentation may assist with maintenance of spawning gravels and this would be assessed through the Project and FAHCE AMP. Monitoring and maintenance of the Spawning Gravel and Rearing Habitat Enhancements in the Live Oak Restoration Reach ~~and the Sediment Augmentation Program~~ would be covered under the SMP and its EIR but considering the extensive BMPs for this program-, the monitoring and maintenance would have short-term less than significant impacts on and long-term benefits to the steelhead population.

Monitoring and Maintenance of Sediment Augmentation Program

The Sediment Augmentation Program would improve geomorphic processes within the CWMZ and reduce and reverse channel incision, benefiting steelhead and their critical habitat. Combined with Spawning Gravel and Rearing Habitat Enhancements in the Live Oak Restoration Reach, these improvements would support a larger and more resilient steelhead population in the watershed.

Valley Water would inspect sediment augmentation sites within the CWMZ, with particular but not exclusive focus on the Live Oak Restoration Reach and the Ogier Ponds creek channel area, to determine if sediment maintenance is required to address incision or fine sedimentation following large flow events. Maintenance would include placing 5 to 500 cubic yards of coarse sediments within Coyote Creek. Sediment augmentation piles would be placed adjacent to the channel with the toe of the pile interacting with the channel within the CWMZ. Monitoring and maintenance of the Sediment Augmentation Program would be covered under the SMP and its EIR but considering the extensive BMPs for this program, the monitoring and maintenance would have short-term less than significant impacts on and long-term benefits to the steelhead population.

Phase 2 Coyote Percolation Dam CM Operations, Maintenance, and Monitoring

Upon completion of both phases of the Coyote Percolation Dam and Fish Ladder renovations, the facility will meet NOAA Fisheries WCR Anadromous Salmonid Design Manual (NMFS 2023 ~~2022~~) and provide safe, effective, and timely upstream and downstream passage of anadromous salmonids regardless of whether the bladder is either inflated or deflated. Fish migration will occur through the existing fish ladder when the dam is inflated. Fish migration will occur via the roughened channel constructed during Phase 2 when the dam is deflated. After restoration of creek flows to the roughened channel, ongoing maintenance would be necessary. Maintenance activities would include periodic removal of sediment deposited in the restored channel which may compromise the channel's conveyance capacity, result in geomorphic instability, or be detrimental to the quality of aquatic habitat. Vegetation management would include removal of invasive plants which compete with native plants and detract from the ecology of the creek habitat and trimming and/or removal of growth clogging the channel. Maintenance staff would also inspect the roughened channel at periodic intervals, particularly after large flows, and replace roughness elements and/or repair in-channel bio-engineered habitat enhancements (e.g., root wads, stream barbs, overhanging banks), and rock slope protection as needed to maintain channel function and maintain fish passage conditions.

Monitoring and maintenance of the Coyote Percolation Dam, associated appurtenances, and adjacent stream channels that interact with the facility would be covered under the DMP and the SMP and their CEQA documents but considering the extensive BMPs and mitigation measures for these programs, the monitoring and maintenance would have short-term less than significant impacts on and ~~long term~~ long-term benefits to the steelhead population.

Within ~~By March 2024~~ 13 months of completion of the Phase 2 Coyote Percolation Dam design, Valley Water would have a completed operations plan for the facility. The objectives of the Operations Plan will be to meet CDFW and NFMS fish passage criteria and to protect out-migrating smolts. Studies would be conducted on juvenile fish passage and predation risk through the pond complex post-enhancements to assess if additional changes are necessary to improve juvenile out-migration.

Key elements of the operations plan to meet anadromous fish passage criteria will include the following:

- Operational flexibility to temporarily drain the Coyote Percolation Pond to improve smolt migration when logistically practicable given water supply demands and ecologically appropriate in terms of habitat management to protect steelhead and other listed and sensitive aquatic and riparian species.
- Upstream passage through the Coyote Creek Percolation Dam Facility will be provided at flows between 2.5 cfs and 1,320 cfs.
- The bladder dam will be inflated when Coyote Creek flows arriving at the dam are less than 275 cfs and upstream passage will be provided through the Fish Ladder.
- When the dam is inflated, Fish Ladder flows will be maintained between 2.5 and 25 cfs during the steelhead migration season and flows above 25 cfs (and less than 275 cfs) will be released through the new ~~bypass gates~~ overshot weir replacing one of the existing radial gates.
- During summer periods outside of the steelhead migration season, the weir gates in the Fish Ladder may be raised to cut off flows to the fish ladder and allow inspection and maintenance activities to be conducted. Valley Water will maintain the minimum required flows per the LSAA to Coyote Creek.
- The bladder dam will be deflated when Coyote Creek flows arriving at the dam are greater than 275 cfs and upstream passage will be provided by the roughened channel.
- When the dam is deflated, Coyote Creek flow greater than 275 cfs arriving at the dam will go over the deflated dam, a portion of this flow will go into the roughened channel to provide upstream passage, and under normal operating conditions, the Fish Ladder and bypass gates will be closed.

The Operations Plan will also address the potential entrainment and predation of salmonid smolts to assure that CDFW (Love and Bates 2009) and NMFS (2023 ~~2022~~) fish passage criteria are attained. The plan will include an evaluation of conditions that impact salmonid smolt migration through the Coyote Percolation P~~p~~ond and will include measures to ensure improved migration conditions including depth, velocity, and predation risk as compared to baseline operation ~~a~~ following implementation of Phase 2 designs. (See Appendix D ~~C~~). The Phase 2 Coyote Percolation Design and Operations Plan will improve post-construction migration opportunities for adults and smolts~~-~~, thereby benefitting steelhead.

Project and FAHCE Adaptive Management

The Project and FAHCE AMP is summarized in *Section 2.10 Project and FAHCE Adaptive Management Program*. The Project and FAHCE AMP was developed in accordance with the FAHCE Settlement Agreement which is aimed at supporting healthy steelhead and Chinook salmon populations as appropriate in three watersheds, including Coyote Creek. Therefore, the AMT will be evaluating monitoring results and performance criteria and identifying adaptive management flow and non-flow measures that benefit steelhead when performance criteria are not met (see Appendix D).

Data will be collected on reservoir elevations, flow releases, depth at critical riffles, and temperature to evaluate compliance and effectiveness of reservoir operations (Appendix D). This information will guide discussion and aid the decision-making process regarding operations.

By definition, the Project and FAHCE AMP would benefit steelhead over the long-term; however, there may be some less-than-significant impacts associated with the implementation of adaptive management measures for both flow measures.

With regard to flow measures, they would be implemented to provide an overall benefit to the steelhead population but there may be impacts to certain life stages or habitats in certain contexts, particularly when water supply is limiting, and one life stage may need to be prioritized over a life stage that is not habitat limited. For example, water may need to be held back in the reservoir in the summer to maintain a cold-water pool throughout the dry season. In this example, there may be an impact to steelhead habitat through decreases in juvenile rearing wetted area to provide cooler water. The AMT would not identify and recommend a change in flow measures if the overall result for the steelhead population would not be beneficial because that would undermine the purpose of the Project and FAHCE AMP. Overall, the impacts associated with flow measures would be less than significant.

Non-flow measures, including the Live Oak Restoration Project, Ogier Ponds, ~~north channel extension project,~~ and the Phase 2 Coyote Percolation Dam CM will be monitored to assess if they have met their specified habitat, jurisdictional area, and ecological functions and services success criteria defined in accordance with respective habitat restoration plans and permitting. After meeting habitat success criteria, long-term adaptive management of the non-flow habitat restoration measures, will be conducted pursuant to the Project and FAHCE AMP, and, if they are not meeting measurable objectives or not functioning as intended, management measures identified in the AMP (Appendix D) and selected in consultation with the AMT would be implemented to meet the objectives or intended function. These refinements of non-flow measures would likely have impacts similar to those discussed in this EIR under Conservation Measures Construction and Conservation Measures Monitoring and Maintenance but at a much smaller scale for Ogier Ponds and the Coyote Percolation Dam. Therefore, some short-term impacts would be predicted if there are any in-channel construction components in any given adaptive management measure and long-term benefits would be predicted, since the AMP is aimed at enhancing steelhead and salmon habitat over the long-term. Logically, the AMT would not recommend an adaptive management measure, if it would not benefit steelhead long-term.

Also, under the AMP, there would be compliance monitoring, validation monitoring, <u>effectiveness monitoring,</u> and a long-term trend monitoring program. Compliance and validation monitoring would collect data through passive monitoring technology and habitat surveys and would have no impacts on steelhead.

Long-term trend monitoring would have noninvasive monitoring and some minimally invasive monitoring methods. Non-invasive monitoring would include passive monitoring such as VAKI Riverwatchers or PIT tag antennas using noninvasive technology which would have no impacts on steelhead. Long-term monitoring would also include stunning through electrofishing, capturing/netting, crowding, handling, DNA sampling, and PIT tagging. These activities can cause acute physiological stress and occasional (but rare) incidental injury and/or mortality. Electrofishing would follow standard NMFS guidelines (NMFS 2000b) and protocols, which would minimize injury and mortality during stunning, handling, sampling, and tagging.

Despite some impacts, the monitoring program would provide valuable long-term individual and population information for steelhead and their habitat the results would be used to adjust components of the Project through the AMP to be more beneficial to steelhead over the long term. Therefore, the impacts of monitoring activities implemented under the AMP would not be substantial.

As described in **Table 2-1** *Project Components*, implementation of a Geomorphic Flows Plan would occur as part of future adaptive management phases of the FHRP and will require additional CEQA assessment and other regulatory approvals. <u>The Geomorphic Flows Plan would interact with the other conservation measures to achieve the following physical channel maintenance objectives downstream of Anderson Dam: mobilize substrate, scour and transport fine sediments, maintain unembedded gravel, support gravel bar formation, reduce riparian vegetation encroachment, support formation of inset benches and floodplains, increase channel migration and bank erosion, and create and maintain a wider active channel and topographic diversity.</u>

Overall, the Project and FAHCE AMP would benefit steelhead. Any adaptive measures with a flow “trade-off” between steelhead life history stages or non-flow measure with an in-stream construction component would have less than significant impacts on steelhead and both types of measures would have long-term benefits. Adaptive management of non-flow habitat restoration Conservation Measures would have impacts similar to those described for maintenance and operations and with BMPs and mitigation, measures would be less than significant, while the construction and operation of the Conservation Measures would benefit steelhead.

Significance Conclusion Summary for Central California Coast Steelhead

The Project would result in certain construction phase impacts on steelhead from Seismic Retrofit Construction, Conservation Measures Construction, and Construction Monitoring. In the post-construction phase, there would also be some impacts from Anderson Dam and Conservation Measures monitoring and maintenance, Post-Construction Instream Flows Operations (FAHCE rule curves), and the Project and FAHCE AMP. These impacts would be **less than significant.**

The Project would benefit steelhead over the long-term through Seismic Retrofit Construction and Post-Construction Operations, Monitoring, and Maintenance; Conservation Measures Construction and Post-Construction Operations, Monitoring, and Maintenance; Construction Monitoring; Post-Construction Instream Flows Operations (FAHCE rule curves); and Adaptive Management.

Overall, any adverse impacts on steelhead would be periodic and temporary, and less than significant during the construction phase. The Project would benefit steelhead in the long-term through increased and enhanced habitat supporting a larger and more resilient steelhead population. The overall impact to CCC steelhead is **less than significant.**

Mitigation Measures

No mitigation is required.

Impact FR-1b: Chinook Salmon (Less than Significant)

This section analyzes the Project's impacts on Chinook salmon and their habitat which includes chinook salmon EFH. Impacts on Chinook salmon EFH are expected when impacts on Chinook salmon habitat is discussed below.

Seismic Retrofit Construction

Seismic Retrofit Construction Activities

Seismic Retrofit construction activities could impact Chinook salmon individuals or their habitat from immediately downstream of the dam to Alviso Slough. Seismic Retrofit construction activities upstream of the dam in the reservoir would not impact Chinook salmon individuals directly, as they are not present in this area. However, there would be increased sediment transport compared with the existing conditions baseline downstream of the dam for the same reasons outlined for *Impact FR-1a: Steelhead* and impacts from increased sediment transport are analyzed in the next section *Instream Flows during Seismic Retrofit Construction* while this section analyzes the impacts of construction activities.

Impacts on Chinook salmon from Seismic Retrofit construction activities (pile driving, earth moving, construction of roads, etc.) would be minimized through the dry season work window as defined in *Section 2.5.1.1 – Schedule*. BMP BI-2 would also protect Chinook salmon by avoiding routine use of vehicles and equipment in Coyote Creek downstream of Anderson Dam between January 1 and June 15.

Seasonal timing is important for Chinook salmon life-history stages and few Chinook salmon would be present in Coyote Creek during the dry season work window because adults migrate upstream after there is hydrologic connection with the ocean influenced by precipitation events (i.e., usually after mid-October and outside the dry season work window) and most juveniles are expected to outmigrate primarily before the start of the dry season work window. Juveniles do not over-summer in freshwater, so no impacts are expected for Chinook salmon from in-channel construction activities because all Chinook salmon should have outmigrated from the system before conditions are dry enough to perform localized dewatering for instream work. In the rare chance that Chinook salmon are present during localized dewatering, there is the potential to strand Chinook salmon or trap them in pools, subjecting them to increased predation pressure and water quality degradation. Chinook salmon could also be taken up into water pumps used to dewater surface water or bypass water around the work area. To minimize these impacts, Chinook salmon would be rescued and relocated during localized dewatering according the relevant approved aquatic species rescue and relocation plan for dewatering activities. <u>Downstream of the dam,</u> BMPs GEN-35 and WQ-3, as well as AMM-17, require any pumps that are used for either dewatering or diverting waters around the work area to be screened, in accordance with NMFS and CDFW criteria, to prevent the uptake of fish, and minimize the potential for fish to be injured and/or killed during the dewatering process. Therefore, impacts from localized dewatering would not be significant.

Rescue and relocation plan capture methods could include backpack electrofishing, seining, dip netting and/or capturing by hand. Impacts to fish may include stunning, netting, capturing, and handling, all of which may cause acute physiological stress that is temporary. Most fish would be expected to recover. Injury or mortality to fish can happen occasionally, but incidents are rare. Most Chinook salmon tolerate short duration capture and handling.

The Invasive Species Monitoring and Control Plan and AMM-91 may also reduce predation pressure and/or competition from nonnative fish, crayfish, American bullfrogs, and red-eared sliders in these areas, at least in the short-term (long term benefits are less likely unless eradication is achieved). BMP BI-11 and AMM-90 will further minimize impacts from predators by requiring that trash be removed daily from the construction area, limiting attraction to the site by terrestrial predators.

Full dewatering of Anderson Reservoir from deadpool to the construction season elevation (465 feet in Year 1, 460 feet in Year 2) would occur during the spring (likely in the last half of April) through the Stage 1 diversion system. The resulting increase in flows downstream of Anderson Dam would benefit Chinook salmon by increasing the magnitude and duration of spring flows suitable to support downstream smolt migration.

Construction activities also have the potential to degrade water quality downstream of the work area due to increased suspended sediment or other materials in the water which could impact Chinook salmon located downstream of the dam. BMPs GEN-20 and WQ-16, as well as AMM-66, AMM-84, and AMM-97 will reduce sediment entering the channel from the work area during precipitation events by installing erosion control measures (e.g., silt fences, straw bales, etc.) and visually inspecting erosion control measures during and following extended storm events. BMPs GEN-26, GEN-31, GEN-30, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, AMM-11, and AMM-100 will minimize the pollution from vehicle fluids or other oily, greasy, or sediment-laden materials that could enter the creek from the work area by maintaining clean conditions at work sites, keeping spill kits available onsite to clean up any accidental spills, training personnel to properly use spill kits, fueling and cleaning vehicles and equipment off site, utilizing secondary containment for any fluid changes on site and storing contaminating materials, keeping vehicles maintained and clean, and inspecting vehicles and equipment daily for leaks prior to initiation of work. BMP WQ-15 will protect Chinook salmon downstream of the work area from impacts of degraded water quality by keeping any oily, greasy, or sediment-laden substances away from places they may enter the waterway and monitoring water turbidity changes downstream of the work area and any discharge points.

In Year 5, blasting at the BHBA site would have the same impacts on Chinook salmon as described for steelhead throughout Year 5 (11 months) but only during the months outside of the work window that the blasting would overlap Chinook salmon occurrence in freshwater habitat. For the same reasons described for steelhead, overall impacts on Chinook salmon from noise and vibration from blasting at the Basalt Hill Borrow Site would be less than significant.

Construction of the 1,300-foot-long access road on the downstream slope of the dam and establishing staging and stockpiling areas would have the same impacts on Chinook salmon as for steelhead and the same BMPs would be implemented and impacts for both would be less than significant for the same reasons as those provided for steelhead for these activities. Following demolition, disturbed areas will be restored to pre-construction conditions and seeding will occur to replace removed vegetation through BMP REVEG-1. Reestablishing native vegetation and riparian habitat would benefit Chinook salmon in the long-term by shading the creek and providing habitat complexity. Additionally, the retrofitted dam would be allowed to refill once ~~seismic~~ restrictions are lifted allowing more storage for cold water pool management post-construction compared to the existing conditions baseline, which would benefit Chinook salmon by allowing more consistent suitable rearing habitat at the end of their rearing period. Finally, the seismically retrofitted dam would have a new, multi-level intake structure that would allow more precise temperature control on downstream releases benefiting Chinook salmon relative to the existing conditions baseline in the long term.

Overall, Seismic Retrofit construction activities may adversely impact Chinook salmon but the impacts would not be substantial with the application of BMPs, AMMs, the dry season work window, and the aquatic species rescue and relocation plans for any in-channel work that requires localized dewatering; therefore, Seismic Retrofit construction impacts from the above-described construction activities would be less than significant on Chinook salmon and their habitat in the short-term. The complete retrofitted dam would benefit Chinook salmon in the long term relative to existing conditions.

Seismic Retrofit (Anderson Dam) and Instream Flows Operations during Seismic Retrofit Construction

This section analyzes the impacts of instream flows downstream of Anderson Dam during Seismic Retrofit construction on Chinook salmon and their habitat compared with the Pre-FERC Order Baseline and existing conditions baseline (post-FOCP). During Seismic Retrofit construction, generally, there would be wet seasons, spring reservoir drawdown, and dry construction seasons (i.e., dry season work window). During the wet season, the outlet of the dam would be fully open and all inflows to the reservoir would be diverted and released downstream as quickly as possible given the type of diversion (Stage 1 or Stage 2). In April, or when conditions allow following April, the reservoir would be drawn down to the elevation needed to conduct construction activities during the dry construction season. The rate of drawdown would depend on antecedent conditions in the watershed and the type of diversion in place (Stage 1 or Stage 2) but should take about 2-4 weeks. Once the reservoir has been drawn down to the correct elevation to initiate in-channel work, then the construction activity for that year would commence and any inflows coming into the reservoir would be diverted (or sometimes pumped) around the work area and released downstream. The sections below assess hydrologic and water quality impacts to all Chinook life stages using simulated storm events in a sediment transport model. Significance conclusions are based on a comparison to Pre-FERC Order Baseline as this represents conditions before any project influence has occurred. This allows for an analysis to assess the true impacts associated with all project activities**.**

Hydrology

Chinook salmon start their migration into Coyote Creek at the beginning of the wet season, potentially at a time that reservoir would start to receive inflow under existing conditions. During the wet season, flows would be bypassed through the reservoir as discussed in the steelhead section. The increased flashiness compared to Pre-FERC Order Conditions in Coyote Creek hydrology that was discussed for steelhead and in *Section 3.11 Hydrology* would benefit migrating, spawning, and rearing Chinook salmon unless suspended sediment is too high (see *Water Quality – Sediment Transport During Wet Seasons and Spring Drawdown* below).

Also, water released for recharge from both the CDL and the Cross Valley Pipeline Extension would incidentally benefit Chinook salmon migrating into the system, spawning, incubating, and rearing because it would keep the groundwater levels higher and help form a quicker connection to the ocean when the precipitation season starts and raises surface water levels to the point that Chinook salmon can safely migrate into the system. The same flows would also help keep the creek wetted which could support outmigrating juveniles. Also, the winter bypass flows, and spring drawdown would occur during the time when Chinook salmon are outmigrating so the brief pulse of water during the drawdown would encourage Chinook salmon smolts to migrate out of the system and to the ocean.

Chinook salmon are not in the system during the more hydrologically limited dry season so they would not be impacted by drier conditions during the dry season from lower flows relative to Pre-FERC Order Baseline. Consequently, there would be no adverse impacts on Chinook salmon or their habitat from changes in hydrology during construction.

Water Quality – Dissolved Oxygen and Temperature

Dry Construction Seasons

In-stream elevated temperatures typically occur only in the dry season. Due to the semelparous nature of Chinook salmon, adults are not present in the system in the dry season as they die after spawning. Juvenile Chinook salmon only rear for 1 to 7 months in freshwater (Moyle 2002) and are expected to migrate downstream prior to the in-channel work window and commencement of the dry season. Adult Chinook salmon do not return to the Creek until flows are high enough to support migration, which would usually happen following precipitation events occurring well into the wet season, when temperatures are lower and DO is adequate. Chinook salmon would not be present in the system during the dry season work window; therefore, they would not be exposed to limiting temperatures so there would be no impacts on Chinook salmon from dissolved oxygen and temperature associated with dewatering and construction phase hydrology.

Water Quality – Construction Phase Hydrology Sediment Transport

Sediment in Wet Season Conditions

Impacts on Chinook salmon and their habitat from sediment transport during wet seasons and spring drawdown would be nearly the same as steelhead but with a few differences discussed below.

Only a small percentage of Chinook salmon adults would be exposed to suspended sediment levels that would impair fitness during construction phase hydrology for the Project. Chinook salmon adults start migrating into Coyote Creek in the fall once there is, and if there is, enough hydrologic connection to migrate through the lower river (usually starting sometime between October-January). Most 2-year, 5-year, or multiple days of inflow at 180 cfs that modeling indicates produce substantial sediment concentrations in bypassed flows would occur later in the season around February and thereafter when most Chinook adults would have already migrated into Coyote Creek spawned and died.

Also, in most years, the number of Chinook salmon documented in the adjacent Guadalupe River Watershed is much higher than Coyote Creek likely due to the higher flow levels derived from the Guadalupe River Watershed at the time of adult migration. A portion of the population of adult Chinook salmon in Coyote Creek and Guadalupe River Watersheds are a result of hatchery strays that were released to San Francisco Bay or the Pacific Ocean as juveniles reared in a hatchery. Due to this release method they did not imprint on a natal river; therefore, homing is often driven by attraction flows. These Chinook can select either watershed. In that context, Chinook salmon adults are most likely to select the watershed with the most attraction flow and suitable/optimal water quality. Usually Guadalupe River Watershed would have more flow during the adult migration season than the Coyote Creek Watershed. Newcombe and Jensen (1996) compiled multiple studies that show that behavioral avoidance and “impaired homing” (which could also be interpreted as behavioral avoidance) are the initial impacts to salmonids as sediment concentrations rise approaching stress-inducing levels. Behavioral avoidance is the logical first level of impact from an evolutionary standpoint because organisms seek to maximize their reproductive fitness, so avoiding stressful conditions during reproduction for themselves or their offspring would be adaptive behavior in salmonids. Therefore, if high levels of sediment are transported out of the Coyote Creek Watershed at a given time, Chinook salmon adults, particularly hatchery strays, could easily select the immediately adjacent Guadalupe River Watershed for migration and subsequent spawning. It is even possible that they can start to ascend Coyote Creek and turn around and swim back out of the Coyote Creek Watershed should sediment levels rise, and they have not been in freshwater long. That said, there is likely a point of trade off where a Chinook salmon is behaviorally “committed” to the migration in that watershed and the risks of changing watersheds outweigh the benefits of avoiding stressors in the watershed they are already in. In that case the Chinook salmon adults would be subject to the elevated sediment levels and would have to rely on other behavioral (coughing) and physiological (increased mucous production on the gills) options for coping with the stressor until conditions improve or until they reproduce and die. While this kind of coping would likely decrease reproductive fitness to some extent, the modeling suggests that sediment levels would not reach a point where the adult Chinook is predicted to die before reproducing (Appendix F).

The modeling predicts that during back to back 2-year events with Stage 1 Diversion and 2-year to 5-year flow events with the Stage 2 diversion, if adult Chinook salmon choose to migrate up Coyote Creek and are committed to the migration in that watershed, the elevated suspended sediment exposure would result in minor to moderate physiological stress, increased rates of coughing, and increased respiration rates. However, Chinook salmon are more likely to spawn further downstream of Ogier Ponds where impacts from suspended sediment would be lower than the model calculations for the FCWMZ, which were the numbers used in this analysis. The suspended sediment impacts would be lower downstream of Ogier Pond because construction scheduling keeps Ogier ponds in place through the Stage 1 and Stage 2 diversions, and Metcalf ponds remain in place. A substantial portion of the increase in suspended sediment would be expected to be trapped in the ponds. Therefore, the impacts predicted from the modeling and severity of ill effects analysis in Appendix F are likely overestimates of the impacts to fish downstream of Ogier Ponds. The model predicts that sediment levels at Milpitas would usually be about half of the levels in the FCWMZ; therefore, in the parts of the lower river where Chinook salmon could inmigrate into the lower reach of the Creek and spawn, an intermediate level of suspended sediment would be predicted and likely closer to the levels at Milpitas because of sediment settling in Ogier and Metcalf Ponds. In this case, both the exposure concentration and duration would be lower than assumed in the analysis and impacts that are already sublethal would be reduced.

Also, back-to-back 2-year, 2-year, and 2-year and 5-year storm events and storm events that would result in 180 cfs of constant inflow over several days (14 days was assumed in the analysis in Appendix F) are not likely at the beginning of the adult migration season October-January. When those storms occur, many adults will have migrated out of the watershed. Also, early season storms tend to be more “flashy” with a quick rise in flow, and associated suspended sediment, followed by a rapid decrease in flow and sediment; therefore, even if adults were present, elevated suspended sediment exposure would have limited duration. As for the rest of the adult migration season, a 2-year event would be predicted to occur 3-4 times and a 5-year event is predicted to occur once during the 6 years of wet seasons with the Stage 2 diversion and both are more likely to occur toward the end of the adult migration season as is the case for any weather conditions that would result in 180 cfs of constant inflow over several days.

Although stress physiology is complex in vertebrates, there is evidence that elevated physiological stress during migration can lower reproductive fitness (Couch et al. 2022), so sediment could impact spawning by chinook that are committed to migration up Coyote Creek during the construction phase notwithstanding the presence of increases suspended sediment. However, there is also evidence that semelparous species (species that die following reproduction) are less sensitive to acute stressors when they start the process of redirecting energy away from nonessential processes like growth and immune system function and toward reproductive effort, such as developing gametes, building redds, and displaying territorial behavior during mating (e.g., Raby et al. 2013). That said, some decrease in fitness of inmigrating and spawning adults would be expected due to physiological stress from elevated sediment transport during construction years, but it would not be substantial.

Finally, a portion of the Chinook salmon observed in Coyote Creek are hatchery strays reducing the dependence on natural reproduction within the watershed to maintain an adult population. The external source of returning adults will continue to result in a return of Chinook salmon even if a reduction of natural reproduction occurs.

For all the reasons described, impacts from increased sediment transport are likely negligible at the population level compared with the Pre-FERC Order Baseline for the annual expected number of Chinook salmon adults with or without the Project.

Juvenile Chinook salmon hatch, rear, and outmigrate in the same year (whereas steelhead juveniles rear year-round for one or more years before outmigrating).

During 2-year and 5-year precipitation events, juveniles would experience minor physiological stress and the effects would be temporary and sublethal but, prolonged physiological stress even if “minor” could result in sublethal effects such as slower growth, decreased foraging efficiency, and increased susceptibility to disease and parasites potentially decreasing their overall fitness during their lifetime. As such, overall reproductive fitness would likely decrease as compared to the Pre-FERC Order Baseline. This level of impact is anticipated to result in sublethal effects to fry and juveniles and would not substantially affect rearing because of low suspended sediment concentration and short exposure duration.

Constant inflow into the reservoir and out to the creek for a prolonged period (91 days was the assumption in the analysis; Appendix F) during the wet season is predicted to increase suspended sediment levels and result in minor physiological stress for juveniles. Minor physiological stress over short durations would have little impact on juveniles but prolonged physiological stress even if “minor” could result in sublethal effects such as slower growth, decreased foraging efficiency, and increased susceptibility to disease and parasites potentially decreasing their overall fitness during their lifetime. However, juveniles may benefit from higher turbidity (caused by elevated suspended sediment) through decreased predation pressure from visual predators as long as the associated suspended sediment is not too high to cause prolonged physiological stress (Newcombe and Jensen 1996, Gregory and Levings 1998, Wilber and Clarke 2001).

For all the reasons described, impacts from increased sediment transport are likely negligible at the population level compared with the Pre-FERC Order Baseline for Juvenile Chinook salmon.

Incubating eggs could experience 0-20 percent mortality during 2-5-year flow events, back-to-back 2-year flow events, and during constant flow of 180 cfs for a prolonged time likely due to smothering and anoxic conditions (see Appendix F). Like steelhead, these impacts are likely overestimates given the low likelihood of sustained 180 cfs constant inflows during the migration and spawning season as well as the incubation period. Also, even with mortality of eggs, Chinook salmon females spawn up to 3,500-5,000 (Healey and Heard 1983 ~~1984~~, Healey 1991) eggs at a time. Therefore, some egg mortality is likely but would not be substantial over the full Project timeline.

Like steelhead, modeled flow events during the construction phase could lead to deposition in limited areas that would increase pool depths, reduce spawning gravel quantity and quality, reduce access to low-terrace floodplain habitat from increased channel incision, and reduced BMI production, but only in a few areas within Coyote Creek (Appendix F) and there would still be habitat for Chinook salmon in other areas. Lower quality spawning habitat and reduced BMI production (food supply for rearing juveniles) may reduce the survival of incubating eggs as well as the growth of fry and juveniles rearing within these limited areas. Chinook salmon can spawn in the lower portions of Coyote Creek where sediment deposition will be less. This ability to use other areas of the system and still be successful reduces potential impacts associated with sediment deposition.

Although it would not be possible to always avoid temporal impacts to incubating Chinook salmon and their habitat in the short-term from increased sediment transport and deposition, Valley Water would conduct continuous suspended sediment monitoring [10] and annual sediment deposition monitoring to inform and implement ~~the Sediment Augmentation Program, and maintain~~ maintenance of spawning habitat substrate through the Live Oak Restoration Project reach, created during FOCP and which will be in place before this Project starts. The spawning gravel ~~Sediment Augmentation Program and~~ maintenance of Live Oak Restoration Reach would be ongoing during seismic retrofit construction of this Project, and then would continue during post-construction monitoring and maintenance in addition to the Sediment Augmentation Program. Therefore, construction phase sediment transport impacts on chinook incubating eggs would be minimized through the ongoing spawning habitat augmentation programs over the long term because gravels ~~and sediment~~ would be replaced as needed based on the monitoring throughout the seismic retrofit construction years, and those monitoring and spawning habitat enhancement ~~e~~ programs along with the Sediment Augmentation Program would continue into the future through adaptive management. This would continue to maintain high quality spawning and rearing habitat during and following seismic retrofit construction.

Sediment in Spring Drawdown and Conditions.

In spring of Years 3, 4, 5, and 6, drawing the reservoir down from deadpool to elevation 450 feet would occur with the Stage 2 diversion allowing up to 6,000 ~~1,000~~ cfs to pass directly through to downstream. Storm events are less likely in April and become less likely thereafter, but smaller storm events can occur during the spring drawdown period; therefore the modeling simulated a

[10] Turbidity would be continuously monitored with a conversion to suspended sediment concentration that will be confirmed through grab samples analyzed for total suspended solids.

2-year storm event in addition to constant inflow into the reservoir and out to Coyote Creek in the absence of a storm event.

Adult Chinook salmon would have already migrated, spawned, and died and eggs would have completed incubation before April so impacts would only be possible for fry and juveniles that would be rearing, smolting, and emigrating to San Francisco Bay around the time that the reservoir would be drawing down. Fry and juveniles could experience moderate physiological stress under both constant inflow and 2-year storm event conditions from increased sediment transport (Appendix F). Moderate physiological stress in fry and juveniles for a prolonged period could result in sublethal effects such as slower growth, decreased foraging efficiency, and increased susceptibility to disease and parasites potentially decreasing their overall fitness during their lifetime. However, fry and juveniles may benefit from decreased predation pressure associated with higher drawdown period turbidity, particularly as the drawdown helps move migrating smolts downstream and out to the San Francisco Bay under the cover of turbid water. Collectively, increased suspended sediment under constant flow and storm events during spring drawdowns would decrease productivity of the natal Chinook salmon population in Coyote Creek during Years 3, 4, 5, and 6 of Project but the presence of immigrating hatchery stray Chinook salmon adults reduces the dependence on natal production, so decreased fitness of natal juveniles may have little impact compared to the Pre-FERC Order Baseline on the Chinook salmon population in Coyote Creek.

Following Year 6, the reservoir drawdown would cease and the reservoir would be allowed to refill via inflows and, if possible, imported water up to the new maximum level. Once filled to an operable level, the FAHCE rule curves would be initiated. With the reservoir refilled, suspended sediment would decrease during constant inflow or precipitation events because the full reservoir would not have exposed erodible sediment at the same level as at the existing conditions baseline and suspended sediment would return to near Pre-FERC Order Baseline and would not be expected to impact Chinook salmon further.

Construction Phase Sediment During Dry Weather Conditions

Existing conditions data indicates that during the Stage 1 drawdown conditions, dry season flows bypassed from Coyote Reservoir to Coyote Creek may contain somewhat higher sediment concentrations than Pre-FERC Order Conditions. Data on sediment concentration Pre-FERC Order Conditions is not available, but due to reservoir conditions under existing conditions and construction increase sediment concentration compared to Pre-FERC Order Baseline is expected. During Stage 2 drawdown, when a greater volume of sediment is exposed due to the lower than deadpool elevation of the reservoir, sediment concentrations in dry season bypassed flows may contain greater sediment than in both existing conditions, and Pre-FERC Order Conditions. No chinook salmon are anticipated to be in Coyote Creek during dry season construction phase conditions because adult salmon will have completed spawning and died, eggs will have completed incubation, and juvenile Chinook salmon are expected to migrate downstream prior to the in-channel work window and commencement of the dry season. Chinook salmon do not return to the upper portions of Creek until flows are high enough to support migration, which would usually happen following precipitation and the adult life history is complete before the main portion of the wet season. Consequently, while sediment concentrations in bypassed flows entering Coyote Creek may be somewhat elevated from those in Pre-FERC Order and/or existing conditions, impacts to Chinook salmon are anticipated to be less than significant.

Overall, sediment concentrations in releases from the reservoir to Coyote Creek, and therefore in instream flows during Seismic Retrofit construction would exceed those in Pre-FERC Order Conditions and could result in periodic., temporary less than significant impacts to Chinook salmon, particularly the egg, fry and juvenile life stages, within the wet seasons and the spring drawdowns during Seismic Retrofit construction. ~~Suspended sediment monitoring, sediment deposition monitoring, the implementation of the Live Oak Restoration Reach Maintenance Conservation Measures and the Sediment Augmentation Programs during construction, combined with higher flow conveyance from the North Channel Extension to reduce erosion and downcutting the South Channel, and t~~ The scheduling of construction to allow continued capture of transported sediments in Ogier Ponds and Metcalf ponds before it travels to the downstream Chinook spawning area would ~~combine to~~ minimize these construction phase impacts. The long term implementation of annual sediment deposition monitoring, the Live Oak Restoration Reach and North Channel Reach Maintenance Conservation Measures, the Sediment Augmentation Program, ~~Conservation Measures, the North Channel Extension Conservation Measures~~ and the Ogier Ponds CM would improve spawning habitat for Chinook salmon as well as steelhead as compared to Pre-FERC Order Conditions ~~s~~, resulting in ~~less~~ a long term net benefit to the Chinook salmon population and its habitat in the long-term.

Non-native Species

For the same reasons outlined for steelhead, impacts from the release of non-native species from Anderson Reservoir downstream to Coyote Creek on Chinook salmon and their habitat would be less than significant compared with the Existing Conditions Baseline as no additional habitat is being created for non-native species and actions are being taken to remove non-natives from the system during construction and monitoring activities.

Instream Flows During Construction Summary

Instream flows during construction would adversely impact all life stages of Chinook salmon and their habitat through increased sediment transport, but the impacts would be less than significant because a large part of the adult Chinook salmon migration season would occur before high flow events, Chinook salmon adults could choose to migrate up other river systems instead, Chinook salmon spawn large numbers of eggs, Chinook salmon can spawn in habitat downstream of Ogier Ponds where sediment impacts are reduced, juveniles can outmigrate during flow events, and hatchery strays would continue to migrate into Coyote Creek irrespective of impacts to incubating eggs. There would be no impact from construction phase hydrology or DO and temperature changes from Pre-FERC Order Baseline on Chinook salmon as no change is expected to occur regarding migration opportunities and temperature compared to Pre-FERC Order Conditions when Chinook salmon are present. Non-native species impacts would have less than significant impacts for the same reasons outlined for steelhead. Over the long term, suspended sediment and sediment deposition monitoring, maintenance of gravel and sediment augmentation programs, and the Ogier Ponds CM, would reverse sediment transport impacts on Chinook salmon habitat and benefit the Chinook salmon population and their habitat.

Conservation Measures Construction

The following Conservation Measures, Normal Operation of Coyote Reservoir and Construction Period Imported Water Releases and Operation of Chillers for Imported Water Releases, do not have a construction component and were previously considered as part of the *Instream Flows during Seismic Retrofit Construction* under the *Seismic Retrofit Construction Activities Impacts Analysis,* so they are not discussed further in this section.

Effects of construction activities for the Conservation Measures that require construction are considered in this section. Conservation measure construction could impact Chinook salmon in the short-term during construction work, but all Conservation Measures were designed to benefit Chinook salmon in the long term. Conservation measure construction components that could impact Chinook salmon are assessed in further detail in this section.

Ogier Ponds CM

Construction activities associated with the Ogier Pond CM that would impact fish and their habitat would occur during in-channel work window and would include localized dewatering and grading in the channel. Implementation of dewatering and aquatic resources rescue and relocation plan and BMP BI-2 will help protect Chinook salmon from stranding during dewatering and from impacts from increased suspended sediment in the channel by restricting in-channel construction activities to the dry season work window, having a plan for native fish rescue and relocation, and minimizing equipment driving in the stream bed. As discussed previously, Chinook salmon are expected to outmigrate before or during the spring drawdown each year. Due to the limited precipitation events, characteristic of Santa Clara County during the end of the migration season, it is expected outmigration will occur before commencement of the in-channel work period. Also, dewatering Anderson Reservoir in April would promote outmigration of juveniles because a flow increase will provide the environmental cue. Chinook salmon would not be present during any of the in-channel construction activities, and it is not expected that these fish would even be encountered during localized dewatering.

Consequently, no impacts are predicted on Chinook salmon or their habitat downstream of Ogier Ponds from changes in instream flows related to localized dewatering (i.e., berming and diverting in-channel flows to accommodate Ogier Ponds CMs in-channel construction work) during in channel work window. Construction activities would not impact water quality downstream of the work area because the work area would be dry prior to the start of construction activities. BMPs GEN-26, GEN-31, GEN-32, WQ-11, and HM-8, as well as AMM-7, AMM-8, and AMM-11, will minimize the pollution from vehicle fluids or other oily, greasy, or sediment-laden materials from entering the channel and washing downstream during high flows when the channel is activated by maintaining clean conditions at work sites, keeping spill kits available onsite to clean up any accidental spills, training personnel to properly use spill kits, fueling and cleaning vehicles and equipment off site, keeping vehicles maintained and clean, and inspecting vehicles and equipment daily for leaks prior to initiation of work.

Also, fish passage would be provided during the wet seasons of the construction phase. Similar to what was described above for steelhead, the Ogier Ponds CM would benefit Chinook salmon in the long term through increased rearing habitat, improved water quality (i.e., lower water temperature), enhanced fish passage, riparian habitat restoration, and reduced habitat for warm water, non-native fish, particularly that of predatory species, in the system.

The restored channel created via the Ogier Ponds CM will operate and function as a natural creek channel. There will be no management of flows or manipulation of features as a result of operations. Weirs will be activated infrequently when flow levels reach 2000 cfs, and there will be spillover, not requiring any actions.

Therefore, with regard to adverse impacts, there would be less than significant construction phase impacts, and the Conservation Measures would benefit Chinook salmon and their habitat long term.

Maintenance of the North Channel Reach ~~*North Channel Extension*~~

~~Construction~~ Maintenance of the North Channel Reach ~~Extension~~ would have the same construction and localized dewatering related impacts on Chinook salmon and their habitat as described for steelhead, but only during the portion of the in-channel work window that overlaps with when migrating juvenile Chinook salmon would potentially be present in Coyote Creek (June 15-June 30). BMPs and ~~PD~~ Project components implemented to reduce impacts from the Conservation Measures on steelhead would also reduce impacts on Chinook salmon. In addition, the majority of juveniles are expected to migrate downstream before the in channel work window. Therefore, impacts to Chinook salmon would be less than significant. ~~Similar to steelhead, Chinook salmon could benefit over the long term from reduced stranding and predation in the existing North Channel pools when they dewater following activation so, with regard to adverse impacts, there would be less than significant impacts on Chinook salmon and their habitat from the North Channel construction, and the Conservation Measures would benefit Chinook salmon and their habitat long term.~~

Maintenance Activities at the Live Oak Restoration Reach

At the end of FOCP (existing conditions baseline), the Live Oak Restoration Reach project will have been completed providing new and enhanced spawning and rearing habitat for Chinook salmon. The maintenance of the spawning gravel and the habitat improvements would continue during and after construction of the Project as a part of the Project. Maintaining this habitat by continued placement of gravel has the potential to degrade water quality downstream of the work area if gravel and associated fine sediment enter the stream at the time of placement, which could impact any Chinook salmon that are in Coyote Creek. The restoration maintenance would have a long-term benefit for Chinook salmon by maintaining spawning habitat enhanced during FOCP. Gravel placement has the potential to impact juvenile Chinook salmon that may be in Coyote Creek during the dry season work window (BMP GEN-1), which is when the in-channel gravel placement will occur. BMPs and AMMs implemented to reduce impacts from the Conservation Measures on steelhead would also reduce impacts on Chinook salmon. In addition, most juvenile Chinook salmon are expected to migrate downstream before the in-channel work window for maintenance under BMP GEN-1. Therefore, adverse impacts associated with gravel placement and maintenance would be less than significant impacts and of short duration. The restoration of gravels within the Live Oak Restoration Reach would have a long-term benefit for Chinook salmon and their habitat by maintaining spawning habitat enhanced during FOCP.

Sediment Augmentation Program

Periodic placement of coarse sediment and gravels to enhance spawning substrate on the benches next to the channel in the CWMZ would have the same impacts on Chinook salmon as described for steelhead. BMPs and AMMs implemented to reduce impacts from the Conservation Measure on steelhead would also reduce impacts on Chinook salmon and their habitat and impacts would be less than significant. The enhanced geomorphic processes that create and maintain spawning habitat within the CWMZ and reduce and reverse channel incision in and downstream of the CWMZ would benefit Chinook salmon and their habitat the same as steelhead. Therefore, adverse impacts associated with gravel placement and maintenance would be period, temporary less-than-significant impacts, and Chinook salmon, like steelhead, will benefit from maintenance of gravels and spawning and rearing habitat over the long-term.

Phase 2 Coyote Percolation Dam CM

Construction activities associated with the Phase 2 Coyote Percolation Dam CM would occur during the in channel work window. It is unlikely that juvenile Chinook salmon will occur in Coyote Creek during the in-channel work window as most juveniles migrating prior to the start of the work window. Sediment and other potential pollutants that may be associated with construction of the Phase 2 Coyote Percolation Dam may enter the channel during construction activities, and would have the same impacts as described for steelhead, but only during the time period when the construction activities would overlap with the Chinook salmon remain present in the creek due to the overlap of the work window and the smolt migration window. BMPs and AMMs implemented to reduce impacts on steelhead would also reduce impacts from sediment on Chinook salmon so that they are less than significant.

Phase 2 improvement including constructing a roughened channel approaching ~~over~~ the dam, replacing one of the radial gates next to the fish ladder with ~~bypass~~ an overshot weir~~s~~, and other modifications to meet the most recent applicable ~~CDFW (Love and Bates 2009) and~~ NMFS (2023 ~~2022~~) and CDFW (Love and Bates 2009) fish passage design criteria, would allow Chinook salmon upstream passage at a wider range of flows and safer downstream passage. Additionally, the ability to operate the dam more quickly during flow would benefit adult Chinook salmon upstream passage by decreasing potential delay in migration timing compared to Pre-FERC Order Baseline Conditions.

Based on the same improved fish passage as steelhead, Phase 2 Coyote Percolation Dam CM would benefit Chinook salmon and conditions for migration downstream of Anderson Dam.

Construction Monitoring

Chinook salmon are not expected to be present during monitoring activities that would cause any disturbance to or affect the channel. Juvenile rearing electrofishing attempts to occur prior to the migration of adult and after outmigration of juvenile Chinook salmon. Surveys are conducted of the channel prior to electrofishing looking for adult Chinook that may be present before this activity and does not commence if they are present. Other monitoring is noninvasive and does not cause any direct impacts to Chinook salmon or their habitat. Therefore, there would be no impact on Chinook salmon from Construction Monitoring.

Post-Construction Seismic Retrofit (Anderson Dam) and Instream Flows Operations (FAHCE Rule Curves)

This section analyzes the impacts and benefits on Chinook salmon and their habitat from implementing the FAHCE rule curves (i.e., the Project) compared with Pre-FERC Order Baseline conditions and Future Baseline conditions based on results of WEAP modeling and Project design objectives for non-flow restoration actions. Benefits of the Conservation Measures, including ~~construction, operations, and maintenance of the North Channel Extension,~~ Phase 2 Coyote Percolation Pond design improvements, Sediment Augmentation Program, Maintenance of Live Oak Restoration and North Channel Reach Conservation Measures and Ogier Ponds CM, are all qualitatively considered in the analysis but are not included in the WEAP Model results. This section provides the relevant summaries of modeled changes in habitat from the WEAP Model output, which are provided with the detailed technical methods in Appendix F.

Spawning and Incubation Habitat

Post-construction operation of the Seismic Retrofit (Anderson Dam) in accordance with FAHCE rule curves is predicted to result in an increase in Chinook salmon spawning and incubation habitat compared with both baseline scenarios.

The WEAP Model predicts 44,515 square feet of incubation adjusted Chinook salmon spawning habitat in Coyote Creek under the Project. Approximately 11,500 square feet of the spawning habitat would occur in the FCWMZ and just over 33,000 square feet would occur in reaches downstream of the FCWMZ. Compared with the Pre-FERC Order Baseline, the Project would result in a 9.6 percent (3,900 square feet) increase in incubation adjusted Chinook spawning habitat across all POIs in Coyote Creek during the entire mid-October through January spawning and incubation period. While the overall change in incubation adjusted spawning habitat under the Project would be positive, the model results vary by location. The WEAP Model predicts that the Project would result in a 15 percent (2,000 square feet) average reduction in incubation adjusted Chinook spawning habitat in the FCWMZ and a 22 percent (5,900 square feet) average increase in downstream reaches compared with the Pre-FERC Order Baseline. The predicted reduction in the FCWMZ is due to reduced flow during portions of the spawning period. Despite the spatial variability in spawning habitat changes under the Project, the overall increase in incubation adjusted spawning habitat in Coyote Creek downstream of the dam would support additional spawners, increase the diversity of available spawning habitat, decrease competition among spawners, and increase resiliency of spawning to temporal and spatial changes in habitat conditions.

Compared with the Future Baseline, the WEAP Model predicts an overall increase in incubation adjusted Chinook spawning habitat under the Project. During the entire mid-October through January spawning and incubation period, the Project would result in a 23.3 percent (8,400 square feet) increase in incubation adjusted Chinook spawning habitat across all POIs in Coyote Creek compared with the Future Baseline. Most of the increase (nearly 8,000 square feet) would occur in reaches downstream of the FCWMZ, with a modest increase (nearly 500 square feet) in the FCWMZ. The predicted increases are due to increased flow during portions of the spawning period, resulting in increased wetted area being available for spawning and incubation. Comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order Baseline because both the Project and Future Baseline scenarios represent conditions occurring at the same point in time (i.e., 2035) and both are based on the same, more updated assumptions regarding water supply and demand, climate change, and other factors affecting flows and habitat in Coyote Creek (see Chapter 5, *Alternatives*). Accordingly, the post-construction FAHCE rule curve operations proposed by the Project would provide to provide substantial benefits to spawning and incubating Chinook salmon.

Comparison of the WEAP Model predictions under the Pre-FERC Order Baseline and the Future Baseline indicates that, without the post-construction operations proposed by the Project, spawning habitat is predicted to decrease in Coyote Creek downstream of Anderson Dam. Under Pre-FERC Order Baseline Conditions, the WEAP model predicts an average total of 40,661 square feet of incubation adjusted Chinook salmon spawning habitat in Coyote Creek downstream of the dam. Under Future Baseline conditions, the WEAP model predicts a total of 36,075 square feet of incubation adjusted Chinook salmon spawning habitat downstream of the dam. This represents a predicted decrease in spawning habitat of 4,586 square feet under the Future Baseline compared with Pre-FERC Order Baseline. This decrease is based on factors that are not related to implementation of the Project or proposed FAHCE rule curves (e.g., changes in conservation, water supply demand resulting in less imported water released into Coyote Creek), and the decrease is predicted to occur without implementation of the Project. In other words, without the Project, spawning habitat in Coyote Creek is predicted to decrease between Pre-FERC Order Baseline and Future Baseline conditions (See Chapter 5, *Alternatives,* for more details). As described above, the Project would also increase spawning habitat in the FCWMZ and downstream reaches compared with the conditions that would occur without the Project (i.e., Future Baseline conditions).

In addition to the modeled changes in spawning habitat under the Project, ~~the maintenance of the Live Oak Restoration Reach,~~ the Ogier Ponds CM,~~ and~~ the Sediment Augmentation Program in conjunction with a maintained North Channel, and the maintenance of the Live Oak Restoration Reach CM ~~that will rely on increased flows through the North Channel Extension~~ would create, enhance, and maintain a substantial amount of Chinook salmon spawning habitat. Spawning habitat created and enhanced by these ~~projects~~ CMs as well as reduced water temperatures downstream of Ogier Ponds during the early fall months (Valley Water 2023b ~~2023c~~) would contribute to additional increases in Chinook salmon production potential in Coyote Creek downstream of Anderson Dam. The increase in spawning habitat would support additional spawners, increase the diversity of available spawning habitat, decrease competition among spawners, and increase resiliency of spawning to temporal and spatial changes in conditions.

Fry Rearing

The Project is predicted to result in an increase in Chinook salmon fry rearing habitat compared with both baseline scenarios.

The WEAP Model predicts over 3.1 million square feet of Chinook salmon fry rearing habitat in Coyote Creek under the Project. Approximately 227,500 square feet of the fry rearing habitat would occur in the FCWMZ and nearly 2.9 million square feet would occur in reaches downstream of the FCWMZ. Compared with the Pre-FERC Order baseline, the WEAP Model predicts a 0.8 percent decrease in fry rearing habitat in the FCWMZ and a 0.6 percent increase in reaches downstream of the FCWMZ, with an overall increase of 15,500 square feet (0.5 percent) under the Project. Compared with the Future Baseline the Project is predicted to increase fry rearing habitat in the FCWMZ and in downstream reaches. Under the Project, the WEAP Model predicts a 2.7 percent increase in Chinook salmon fry rearing habitat in the FCWMZ, a 0.5 percent increase in reaches downstream of the FCWMZ, and an overall increase of 19,700 square feet (0.6 percent) compared with the Future Baseline. While comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order Baseline, the similar Project benefits relative to both baseline scenarios indicate that the project would benefit rearing Chinook salmon fry.

Chinook salmon fry rearing habitat in Coyote Creek, as predicted by the WEAP Model, is present upstream of the Upper Penitencia Creek confluence (POI COYO 2). Changes in Chinook fry rearing habitat between the Pre-FERC Order Baseline and the Project are likely driven by modeled flow-related differences in water velocity and water temperature, both of which affect suitability for fry rearing. Daily average flows in the FCWMZ under the Project would be lower than flows under the Pre-FERC Order Baseline during portions of the fry rearing period, which likely accounts for the decrease in fry rearing habitat in the FCWMZ under the Project. In reaches downstream of the FCWMZ, modeled wetted area increases during portions of the fry rearing period likely drive the predicted increases in fry rearing habitat compared with the Pre-FERC Order Baseline. Changes in Chinook fry rearing habitat between the Future Baseline and the Project are likely driven by modeled flow-related differences in water velocity which affect suitability of fry rearing habitat, and by the total area suitable for fry rearing. Daily average flows in Coyote Creek under the Project would generally be equal to or slightly higher than flows under the Future Baseline during the entire fry rearing period, which would increase the wetted area suitable for fry rearing.

Evaluation of the WEAP Model predictions indicates that Chinook salmon fry rearing habitat is predicted to decrease slightly in Coyote Creek downstream of Anderson Dam between the Pre-FERC Order Baseline and the Future Baseline. Under Pre-FERC Order Baseline Conditions, the WEAP model predicts an average total of 3,102,950 square feet of fry rearing habitat in Coyote Creek downstream of the dam. Under Future Baseline conditions, the WEAP model predicts a total of 3,098,751 square feet of fry rearing habitat downstream of the dam. This represents a predicted decrease in Chinook salmon fry rearing habitat of 4,199 square feet (0.1 percent) under the Future Baseline compared with the Pre-FERC Order Baseline. This decrease is based on factors that are not related to implementation of the FAHCE rule curves (e.g., changes in conservation, water supply demand resulting in less imported water released into Coyote Creek), since the decrease is predicted to occur without implementation of the Project. In other words, without the Project, fry rearing habitat in Coyote Creek is predicted to decrease slightly between Pre-FERC Order Baseline and Future Baseline conditions. The decrease, however, is very small and considering the large amount of fry rearing habitat available in Coyote Creek would be unlikely to influence fry rearing success or Chinook salmon production potential under baseline conditions.

In addition to the modeled changes in fry rearing habitat under the Project, the Ogier Ponds CM would create and enhance a substantial amount of fry rearing habitat in Coyote Creek. Fry rearing habitat created and enhanced by the Ogier Ponds CM would contribute to additional increases in Chinook salmon production potential in Coyote Creek downstream of Anderson Dam. The overall increase in Chinook salmon fry rearing habitat would support additional individuals, increase the diversity of available rearing habitat, decrease competition among rearing individuals, and increase resiliency of rearing to temporal and spatial changes in habitat conditions. Also, the continued Maintenance of the Rearing Habitat Improvements in the Live Oak Restoration Reach <u>and Maintenance of the North Channel Reach</u> would maintain fry rearing habitat through the Project that was improved during FOCP (see Section 3.4.5, *Cumulative Impacts*).

<u>Juvenile Rearing</u>

The Project is predicted to result in an increase in Chinook salmon juvenile rearing habitat compared with the Future Baseline, with a predicted decrease in juvenile rearing habitat relative to the Pre-FERC Order Baseline.

The WEAP Model predicts over 2.5 million square feet of Chinook salmon juvenile rearing habitat in Coyote Creek under the Project during the January–June juvenile rearing period. Approximately 248,000 square feet of the juvenile rearing habitat would occur in the FCWMZ and nearly 2.3 million square feet would occur in reaches downstream of the FCWMZ. Compared with the Pre-FERC Order Baseline, the WEAP Model predicts a 2.2 percent increase in juvenile rearing habitat in the FCWMZ and a 3.9 percent decrease in reaches downstream of the FCWMZ, with an overall decrease of 86,400 square feet (3.3 percent) under the Project. Compared with the Future Baseline the Project is predicted to increase juvenile rearing habitat in the FCWMZ and in downstream reaches. Under the Project, the WEAP Model predicts a 7 percent increase in Chinook salmon juvenile rearing habitat in the FCWMZ, a 1 percent increase in reaches downstream of the FCWMZ, and an overall increase of 38,400 square feet (1.5 percent) compared with the Future Baseline. As described previously, comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order baseline. Accordingly, the Project would benefit rearing juvenile Chinook salmon.

Changes in Chinook juvenile rearing habitat between the Pre-FERC Order Baseline and the Project are likely driven largely by flow-related differences in water velocity, which affect suitability for juvenile rearing. In the FCWMZ and many other reaches of Coyote Creek characterized by a moderate to high degree of channel entrenchment and relatively little floodplain connection, a moderate increase in flow that remains within the channel banks results in higher water velocity but does not typically inundate more juvenile rearing habitat. As a result, juvenile rearing habitat suitability is reduced as water velocity increases beyond the suitable range for juvenile rearing. Changes in Chinook juvenile rearing habitat between the Future Baseline and the Project are likely driven by flow-related differences in water velocity and temperature, both of which affect suitability of juvenile rearing habitat. Daily average flows in Coyote Creek under the Project would generally be equal to or slightly higher than flows under the Future Baseline during the entire January 1 through June 30 juvenile rearing period, which increases wetted area and likely accounts for the increase in juvenile rearing habitat under the Project. In addition, May–June water temperatures under the Project would be lower than the Future Baseline in all reaches. As a result, availability of suitable juvenile rearing habitat under the Project would increase relative to the Future Baseline during this period.

Evaluation of the WEAP Model predictions indicates that Chinook salmon juvenile rearing habitat is predicted to decrease in Coyote Creek downstream of Anderson Dam between the Pre-FERC Order Baseline and the Future Baseline. Under Pre-FERC Order Baseline Conditions, the WEAP model predicts an average total of 2,619,960 square feet of juvenile rearing habitat in Coyote Creek downstream of the dam. Under Future Baseline conditions, the WEAP model predicts a total of 2,495,125 square feet of juvenile rearing habitat downstream of the dam. This represents a predicted decrease in Chinook salmon juvenile rearing habitat of 124,835 square feet (4.8 percent) under the Future Baseline compared with the Pre-FERC Order Baseline. This decrease is based on factors that are not related to implementation of the FAHCE rule curves (e.g., changes in conservation, water supply demand resulting in less imported water released into Coyote Creek), since the decrease is predicted to occur without implementation of the Project. In other words, without the Project, juvenile rearing habitat in Coyote Creek is predicted to decrease between Pre-FERC Order Baseline and Future Baseline conditions. The decrease, however, is small and considering the large amount of juvenile rearing habitat available in Coyote Creek would be unlikely to influence juvenile rearing success or Chinook salmon production potential under baseline conditions.

In addition to the modeled changes in Chinook salmon juvenile rearing habitat under the Project, the Ogier Ponds CM would create and enhance a substantial amount of juvenile rearing habitat in Coyote Creek. Juvenile rearing habitat created and enhanced by the Ogier Ponds CM would contribute to additional increases in Chinook salmon production potential in Coyote Creek downstream of Anderson Dam. The overall increase in Chinook salmon juvenile rearing habitat would support additional individuals, increase the diversity of available rearing habitat, decrease competition among rearing individuals, and increase resiliency of rearing to temporal and spatial changes in habitat conditions. Also, the continued Maintenance of the Rearing Habitat Improvements in the Live Oak Restoration Reach would maintain juvenile rearing habitat through the Project that was improved during FOCP (see Section 3.4.5, *Cumulative Impacts*).

Adult Upstream Passage

The WEAP Model results indicate virtually no change in opportunities for upstream migration of adult Chinook salmon under the Project compared with the Pre-FERC Order Baseline. Similarly, the WEAP Model results indicate very little change in adult migration opportunities under the Project compared with the Future Baseline. Under both comparative scenarios, flows in Coyote Creek under the Project during the October–January adult migration period would typically provide slightly increased opportunities for upstream migration of adult Chinook (e.g., 1 additional day, on average) at some locations, slight reductions in upstream migration opportunities (e.g., 1–2 fewer days, on average) at other locations, and no change at most locations.

While implementation of the FAHCE rule curves under the Project would not substantially change upstream migration opportunities for Chinook salmon, completion of the Ogier Ponds CM would provide additional passage improvements for adult Chinook salmon by disconnecting Coyote Creek from the ponds, reducing pond entrainment and predation risk, reducing instream water temperature, and improving channel conditions in the restoration area. The Phase 2 Coyote Percolation Dam also improves migration conditions but passage at that location is already assumed in the WEAP Model.

Overall, implementation of the Project and the Ogier Ponds CM would improve adult Chinook salmon passage opportunities and contribute to increases in Chinook salmon production potential in Coyote Creek downstream of Anderson Dam.

Juvenile Downstream Passage

Implementation of the FAHCE rule curves under the Project is predicted to increase opportunities for downstream passage of juvenile Chinook salmon compared with both baseline scenarios. Fish passage opportunities in Coyote Creek would also increase as a result of the Ogier Ponds CM (Section 2.6.1).

The WEAP Model results indicate that flows in Coyote Creek under the Project would increase opportunities for downstream migration of juvenile Chinook salmon. Compared with the Pre-FERC Order Baseline, flows under the Project would increase the median [11] number of suitable

[11] For the downstream passage analysis, the median is presented instead of the average because the median better represents the central tendency when the data include multiple zero values (years with zero passage days), as is the case with the WEAP Model results for these two model scenarios.

passage days by 13 (22 percent) and increase the maximum number of days by 8 (8 percent). The minimum annual number of suitable days for downstream passage would increase from 0 under the Pre-FERC Order Baseline to 10 days under the Project, increasing the likelihood of successful outmigration by juvenile Chinook salmon from Coyote Creek.

Compared with the Future Baseline, flows under the Project would increase the median number of suitable days for juvenile Chinook downstream passage by 46 (198 percent). The WEAP Model results indicate the minimum annual number of suitable days for downstream passage would increase from 0 under the Future Baseline to 10 days under the Project. There would be no change to the maximum number of annual suitable downstream passage days (111) under the Project compared to the Future Baseline.

With implementation of the Project and the Conservation Measures including habitat restoration and passage improvements, opportunities for juvenile Chinook salmon downstream passage in Coyote Creek would increase substantially. As described previously, these enhancements would provide additional improvements in passage suitability for both adult and juvenile Chinook salmon that are not accounted for by the WEAP Model results. The Ogier Ponds CM would reduce pond entrainment and predation risk by disconnecting Coyote Creek from the ponds and would improve temperatures for late season migration and decrease migration delay that would improve downstream migration conditions for juvenile Chinook salmon. The Phase 2 Coyote Percolation Dam also improves migration conditions but passage at that location is already assumed in the WEAP Model.

Overall, implementation of the post-construction FAHCE rule curve operations as proposed by the Project and the implementation of the Phase 2 Coyote Percolation design and operations, and the Ogier Ponds CM would improve downstream migration opportunities and contribute to increases in Chinook salmon production potential in Coyote Creek downstream of Anderson Dam.

Post-Construction Instream Flows (FAHCE Rule Curves) Summary

Compared with the Future Baseline, the post-construction instream flows under the Project would have little or no adverse impacts on the Chinook salmon population in Coyote Creek, with likely benefits to production. Compared with the Pre-FERC Order Baseline, the Project would slightly reduce juvenile rearing habitat for Chinook salmon but, as previously described, comparisons with the Pre-FERC Order Baseline do not represent project benefits as accurately as comparisons with the Future Baseline.

Overall, implementation of the FAHCE rule curves in combination with the habitat improvements from the Ogier Ponds CM, the Phase 2 Coyote Percolation Dam design and operations, the Sediment Augmentation Program and continued maintenance of the Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach combined with the maintained conveyance ~~improvements~~ of the North Channel Reach ~~Extension~~ would benefit Chinook Salmon in Coyote Creek.

Post Construction Seismic Retrofit and Conservation Measures Operations, Maintenance, and Adaptive Management Impacts Analysis

Seismic Retrofit (Anderson Dam) Post-Construction Operations, Maintenance, and Monitoring

Chinook salmon and their habitat would have the same benefits from more flexible operations of Anderson Dam as were described for steelhead. These improvements would support a larger and more resilient Chinook salmon population in the watershed. Post-Construction dam releases in accordance with the FAHCE rule curves proposed as part of the Project are discussed in the section above.

Monitoring and maintenance of the Seismic Retrofit facilities would be covered by the DMP and PMP as described for steelhead. Therefore, there would be less than significant short-term impacts on, and long-term benefits to Chinook salmon and their habitat from operations, maintenance, and monitoring of the retrofitted dam.

Ogier Ponds Conservation Measure Operations, Maintenance, and Monitoring

The restored channel created via the Ogier Ponds Conservation Measure will operate and function as a natural creek channel. There will be no management of flows or manipulation of features as a result of operations. Weirs will be activated infrequently when flow levels reach 2000 cfs, and will be spillover, not requiring any actions. These created conditions will benefit Chinook salmon as described in above in Impact FR-1a.~~.~~ Due to the infrequent nature of activation of the spillover weirs, impacts associated with potential entrainment would not cause a reduction in overall production in the species. Chinook salmon and their habitat would have the same benefits from maintenance of the restored channel as were described for steelhead. Maintenance of these improvements would continue to support a larger and more resilient Chinook salmon population in the watershed. Monitoring and maintenance would be covered by the SMP as described for steelhead. Therefore, there would be less-than-significant, short-term impacts and long-term benefits from maintenance, and monitoring of the Ogier Ponds CM.

North Channel Reach ~~Extension Operations,~~ Maintenance~~,~~ and Monitoring

~~Chinook salmon and their habitat would have the same benefits from operation of the North Channel Extension in terms of enhanced passage of geomorphic flows and decreased fish stranding risk as described for steelhead. These habitat improvements resulting from operation of the North Channel Extension would support a larger and more resilient Chinook salmon population in the watershed.~~

Monitoring and maintenance of the North Channel Reach ~~channel extension~~ would be temporary and covered by the SMP as described for steelhead. Therefore, there would be less than significant short-term maintenance impacts on and long-term benefits to Chinook salmon and their habitat from ~~operations, maintenance, and monitoring of~~ maintenance of the North Channel Reach ~~Extension~~ for the same reasons described for steelhead.

Spawning Gravel and Rearing Habitat Enhancements in the Live Oak Restoration Reach and ~~Sediment Augmentation Program~~ Monitoring and Maintenance

Even though the goals and objectives of the spawning gravel ~~and Sediment Augmentation Program~~ are focused on improving spawning and rearing habitat for steelhead, there would be overlap with the gravel sizes Chinook salmon need for spawning. Maintenance would maintain the enhanced spawning and rearing habitat, benefiting Chinook salmon and their spawning habitat. Combined, these improvements would support a larger and more resilient Chinook salmon population in the watershed.

Monitoring and maintenance would be periodic and covered by the SMP as described for steelhead. Therefore, there would be less-than-significant, periodic, short-term impacts on and long-term benefits to Chinook salmon and their habitat from operating, maintaining and monitoring the Live Oak Reach gravel augmentation and rearing habitat enhancements.

Sediment Augmentation Program Monitoring and Maintenance

Even though the goals and objectives of the Sediment Augmentation Program are focused on improving spawning and rearing habitat for steelhead, the general improvement in geomorphic processes in Coyote Creek would benefit Chinook salmon as well. Maintenance would maintain the enhanced spawning and rearing habitat, benefiting Chinook salmon and their spawning habitat. Combined, these improvements would support a larger and more resilient Chinook salmon population in the watershed.

Monitoring and maintenance would be periodic and covered by the SMP as described for steelhead. Therefore, there would be less-than-significant, periodic, short-term impacts on and long-term benefits to Chinook salmon and their habitat from maintaining and monitoring the Sediment Augmentation Program.

Phase 2 Coyote Percolation Dam Fish Passage Enhancements Operations, Maintenance, and Monitoring

Coyote Percolation Dam operations would provide the same benefits to Chinook salmon and their habitat as described for steelhead. These improvements would support a larger and more resilient Chinook salmon population in the watershed.

Monitoring and maintenance would be covered by the DMP ~~and SMP~~ as described for steelhead. Therefore, there would be less than significant short-term impacts and long-term benefits to Chinook salmon, and their habitat, from Phase 2 Coyote Percolation Dam CM operations, maintenance, and monitoring.

Project and FAHCE Adaptive Management

The FAHCE AMP is summarized in *Section 2.10 Project and FAHCE Adaptive Management Program*. The Project and FAHCE AMP was developed in accordance with the FAHCE *Settlement Agreement* which is aimed at supporting healthy steelhead and Chinook salmon populations in three watersheds, including Coyote Creek. Therefore, the AMT will be evaluating monitoring results and performance criteria and identifying adaptive management flow and non-flow measures that benefit Chinook salmon when performance criteria are not met (see Appendix D). By definition, the Project and FAHCE AMP would benefit Chinook salmon over the long-term;

however, there may be some less-than-significant impacts associated with the implementation of adaptive management measures for both flow and non-flow measures.

With regard to flow measures, they would be implemented to provide an overall benefit to the steelhead population and the Chinook salmon population (when benefits to Chinook salmon would not cause adverse impacts to federally listed steelhead). However, there may be less-than-significant impacts to certain life stages or habitats in certain contexts, particularly when water supply is limiting and one life stage may need to be prioritized over a life stage that is not habitat limited or when steelhead habitat needs to be prioritized over Chinook salmon habitat. For example, water may need to be held back in the reservoir in the summer to maintain a cold-water pool throughout the dry season for rearing steelhead, which may result in some flows being held back at the beginning of Chinook salmon migration season. In this example, there may be a less than significant impact to Chinook salmon habitat through decreases in early-season adult migration flows to provide a more important benefit of suitable temperature flows to support rearing steelhead (the federally listed species that relies on year-round rearing habitat). Logically, the AMT would not identify and recommend a change in flow measures if the overall result for the Chinook salmon would be a significant adverse impact, because that would undermine the purpose of the Project and FAHCE AMP.

Non-flow measures, including the Live Oak Restoration Project, Ogier Ponds~~, habitat related elements of the north channel extension project~~, and the Phase 2 Coyote Percolation Dam CM will be monitored to assess if they have met their specified habitat targets, jurisdictional area, and ecological functions and services success criteria defined in accordance with respective habitat restoration plans and permitting. After meeting habitat success criteria, long-term adaptive management of the non-flow habitat restoration measures, will be conducted pursuant to the Project and FAHCE AMP, and, if they are not meeting measurable objectives or not functioning as intended, management measures identified in the AMP and selected in consultation with the AMT would be implemented to meet the objectives or intended function. These refinements of non-flow measures would likely have impacts similar to those discussed in this EIR under Conservation Measures Construction and Conservation Measures Monitoring and Maintenance. Therefore, some short-term impacts would be predicted if there are any in-channel construction components in any given adaptive management measure but only if they overlapped the seasonal times that Chinook salmon could be in the system, which would be rare. Long-term benefits would be predicted under the AMP since the AMP is aimed at enhancing steelhead and salmon habitat over the long term. Logically, the AMT would not recommend an adaptive management measure, if it would result in a significant impact to Chinook salmon.

Also, under the AMP, there would be compliance monitoring, validation monitoring, effectiveness monitoring, and a long-term trend monitoring program (see Appendix D). Compliance and validation monitoring would collect data through passive monitoring technology and habitat surveys and would have no impacts on Chinook salmon.

Long-term trend monitoring would have noninvasive monitoring and some minimally invasive monitoring methods. Non-invasive monitoring would include passive monitoring such as VAKI Riverwatchers or PIT tag antennas using noninvasive technology which would have no impacts on Chinook salmon. The long-term trend monitoring includes stunning through electrofishing, capturing/netting, crowding, handling, DNA sampling, and PIT tagging occurs during times that Chinook salmon are not present in the system.

Despite some impacts, the monitoring program would provide valuable long-term individual and population information for Chinook salmon and their habitat the results would be used to adjust components of the Project through the AMP to be more beneficial to salmon (as long as it is not at expense of listed steelhead) over the long term. Therefore, the impacts of monitoring activities implemented under the AMP would not be substantial.

As described in **Table 2-1** *Project Components*, implementation of a Geomorphic Flows Plan would occur as part of future adaptive management phases of the FHRP and will require additional CEQA assessment and other regulatory approvals. In general, the geomorphic flows would include infrequent high flows sufficient to scour sediment, erode banks, scour vegetation, and result in channel migration in localized areas which would maintain and increase habitat complexity, reduce non-native invasive species (Kiernan and Moyle 2012), and increase benthic macroinvertebrate production benefitting Chinook spawning and rearing and increasing productivity of the population (Cross et al. 2011).

Overall, the Project and FAHCE AMP would benefit Chinook salmon. Any adaptive measures with a flow “trade-off” between steelhead and Chinook salmon or Chinook salmon life history stages or non-flow measure with an in-stream construction component would likely have less-than-significant impacts on Chinook salmon and both types of measures would have long-term benefits.

Significance Conclusion Summary for Chinook Salmon

The Project would result in certain adverse, less-than-significant impacts on Chinook salmon from Seismic Retrofit Project Construction; Conservation Measures Construction; Construction Monitoring; and Anderson Dam and Conservation Measures Maintenance. In the post-construction phase, there would also be some impacts from Anderson Dam and Conservation Measures monitoring and maintenance, Post-Construction Instream Flows Operations (FAHCE rule curves), and the Project and FAHCE AMP. These impacts would be less than significant.

The Project would benefit Chinook salmon and their habitat long term through Seismic Retrofit Operations, Monitoring, and Maintenance; Conservation Measures Operations, Monitoring, and Maintenance; Construction Monitoring; Post-Construction Instream Flows Operations (FAHCE rule curves); and Adaptive Management. Overall, impacts on Chinook salmon would be **less than significant** in the short term with long-term benefits to the Chinook salmon population and habitat.

Mitigation Measures

No mitigation is required.

Impact FR-1c: Pacific Lamprey (Less than Significant)

Seismic Retrofit Construction Impacts Analysis

Seismic Retrofit Construction Activities

Construction activities in the Seismic Retrofit Project Area could impact Pacific lamprey individuals and their habitat from immediately downstream of Anderson Dam to Alviso Slough. Construction activities upstream of the dam in the reservoir would not impact Pacific lamprey individuals directly because lamprey do not occupy the reservoir; however, increased sediment transport associated with dewatering the reservoir and exposing erodible sediment that can be transported during precipitation events could indirectly impact Pacific lamprey individuals and their habitat as is addressed in the next section: *Seismic Retrofit (Anderson Dam) Operations and Instream Flows During Seismic Retrofit Construction*.

Impacts to Pacific lamprey and measures to reduce impacts from out of channel construction that can cause noise and vibration or result in increased runoff of toxic substances and erosion (excavation and fill, staging and stockpiling materials, blasting at the BHBA, and road construction and demolition) would be the same as described for steelhead and the same BMPs and AMMs would apply reducing impacts so that they are less than significant.

Impacts from in-channel work (driving or casting piles in place for temporary bridges and dikes, creation of berms for the Ogier Ponds creek pond separation work, and in-channel work for the Phase 2 Coyote Percolation dam, and localized dewatering to accommodate this work) would have similar impacts on Pacific lamprey as for steelhead but the impacts would be potentially greater because Pacific lamprey migrating adults can be in the study area at any time of year and larvae buried in sediment can be difficult to salvage if present, and may not move out of construction areas on their own volition. However, lamprey larvae have been shown to withstand prolonged periods of dewatering if they can burrow deep enough in the hyporheic zone to remain wetted (Rodriguez-Lozano et al. 2019), making them more resilient to dewatering than salmonid larvae. Aquatic species rescue and relocation plans for localized dewatering activities would reduce impacts, and areas where localized dewatering would occur are very limited. Capture methods would include backpack electrofishing, seining, dip netting, and/or capturing by hand.

The Invasive Species Monitoring and Control Plan and AMM-91 may also reduce predation pressure from nonnative fish, crayfish, American bullfrogs, and red-eared sliders in Coyote Creek, at least in the short-term (long-term benefits are less likely unless eradication is achieved). BMP BI-11 and AMM-90 will further minimize impacts from predators by requiring that trash be removed daily from the construction area, limiting attraction to the site by predators.

Following demolition and upon completion of construction, disturbed areas would be restored to pre-construction conditions and seeding would occur to replace removed vegetation through BMP REVEG-1. Reestablishing native vegetation and riparian habitat would benefit Pacific lamprey in the long term by shading the creek and providing habitat complexity. Additionally, the retrofitted dam would be allowed to refill once ~~seismic~~ restrictions are lifted allowing more storage for cold water pool management post-construction compared to the Pre-FERC Order Baselines, which would benefit Pacific lamprey by allowing more consistent suitable rearing and pre-spawning holding habitat throughout the dry season. Finally, the seismically retrofitted dam would have a new, multi-level intake structure that would allow more precise temperature control on downstream releases benefiting Pacific lamprey relative to Pre-FERC Order and future conditions baselines.

Overall, Seismic Retrofit construction activities may adversely impact Pacific lamprey during the construction phase, but the impacts would not be substantial with the application of BMPs, AMMs, including the dry season work window, construction pollutant controls, and the aquatic species rescue and relocation plans for any in-channel work that requires localized dewatering. Therefore, Seismic Retrofit construction impacts from the above-described construction activities would be less than significant on Pacific lamprey and their habitat in the short-term. The complete retrofitted dam would benefit Pacific lamprey in the long term relative to existing conditions.

Seismic Retrofit (Anderson Dam) and Instream Flows Operations during Seismic Retrofit Construction

This section analyzes the impacts of Anderson Dam operations and instream flows downstream of Anderson Dam during Seismic Retrofit Construction on Pacific lamprey compared with the Pre-FERC Order Baseline and existing conditions baseline (post-FOCP). During Seismic Retrofit construction, generally, there would be wet seasons, spring reservoir drawdown, and dry construction seasons (i.e., dry season work window). During the wet season, the outlet of the dam would be fully open and all inflows to the reservoir would be diverted and released downstream as quickly as possible given the type of diversion (Stage 1 or Stage 2). In April, or when conditions allow following April, the reservoir would be drawn down to the elevation needed to conduct construction activities during the dry construction season work window. The rate of drawdown would depend on antecedent conditions in the watershed and the type of diversion in place (Stage 1 or Stage 2) but should take about 2–4 weeks. Once the reservoir has been drawn down to the correct elevation to initiate in-channel work, then the construction activity for that year would commence and any inflows coming into the reservoir would be diverted (or sometimes pumped) around the work area and released downstream.

Hydrology

Impacts on Pacific lamprey from changes in construction phase hydrology would be less than significant for the same reasons outlined for steelhead. Pacific lamprey have similar migratory triggers but, require less depth for passage and rearing. Any analysis conducted for steelhead will provide a conservative assessment of conditions for Pacific lamprey.

Water Quality – Dissolved Oxygen and Temperature

Impacts on Pacific lamprey from changes in temperature and DO would be less than significant for the same reasons outlined for steelhead, as this species has similar DO and Temperature requirements, but are less sensitive to changes in these parameters. Any analysis conducted for steelhead will provide a conservative assessment of conditions for Pacific lamprey.

Water Quality – Sediment Transport During Wet Seasons and Spring Drawdown

Pacific lamprey have evolved to use various watersheds including flashy watersheds that frequently have high suspended sediment and associated turbidity during and following storm events, particularly the first storm events of the water year (Reid and Goodman 2016a).

Definitions of turbidity and suspended sediment and impacts and benefits of both for fish as well as adaptations that fish can evolve to handle high levels of suspended sediment concentration are described in the Instream Flows During Construction section for steelhead (Impact FR-1a) and are not repeated here.

This analysis used sediment transport modeling to estimate the likely exposure levels (derived from duration and magnitude of elevated suspended sediment) for fish in Coyote Creek during wet weather evens and Stage 1 and Stage 2 diversions. These exposure levels were then translated into the likely impacts predicted for exposed Pacific lamprey in Coyote Creek downstream of the dam under varying conditions (back to back 2-year storm events with Stage 1 diversion or constant inflow, 2-year storm events, and/or 5-year storm events with Stage 2 diversion). The impact analysis described here is a summary of the results with the more detailed methods and analyses described in Appendix F ~~G~~.

Pacific lamprey occur in the mainstem of Coyote Creek as far upstream as the base of Anderson Dam. There is not extensive literature on the effects of suspended sediment on lamprey. This analysis was based on the effects of suspended sediment on salmonids, with the assumption that impacts on lamprey, a very different kind of fish, are likely less than or equal to those on salmonids. It is generally observed that most life stages of Pacific lamprey are more resilient to poor water quality than salmonids (Zaroban et al. 1999), so these assumptions are likely conservative.

During the wet season in Years 1 and 2 and back-to-back 2-year storm events (or equivalent events), migrating adult Pacific lamprey could experience moderate physiological stress compared to Pre-FOCP conditions (Appendix F ~~G~~). If temporary, moderate physiological stress usually has negligible long-term impacts on an animal and are often seen as adaptive responses that allow an animal to cope with a stressful event (Sapolsky 2021 ~~2004~~). However, moderate physiological stress across long durations can result in sublethal impacts like impaired reproduction and increased susceptibility to disease and parasites. Pacific lamprey could behaviorally regulate their exposure and choose not to enter and migrate up Coyote Creek, potentially migrating up a different watershed to reproduce or they may continue to migrate up Coyote Creek and attempt to reproduce there. Pacific lamprey do not home to natal rivers (Spice et al. 2012) so there would likely be little consequence if migrating adults select another watershed for migration during Project construction. Also, Pacific lamprey die after spawning and are already experiencing high physiological stress as their bodies prepare to mate, spawn, and die so slight increases in physiological stress during their final migration would have a negligible impact on migrating adult lamprey.

Based on impacts to salmonids, an SEV of 10 is predicted for larval rearing under Scenario 2 with back-to-back a 2-year flow (or equivalent) events. An SEV of 10 for juvenile salmonids is predicted to result in 0-20 percent mortality, but because Pacific lamprey larvae can rear in burrows in fine sediment (Stillwater 2014), they may tolerate spikes in suspended sediment resulting from the Project, although excessive sedimentation from the settling out of suspended fines could possibly smother larvae in some areas. Pacific lamprey larvae are filter-feeders (Stillwater 2014), so reduced growth rates might be expected from elevated suspended sediment. However, the broad spatial distribution of Pacific lamprey in the Coyote Creek Watershed, including Upper Penitencia Creek, should mean that a large portion of the rearing larva population would not be impacted by the Project. In addition, larvae that rear downstream of Ogier Ponds would be exposed to lower levels of suspended sediment (down to about half) as a result of dilution from additional sources of flow and deposition within Ogier, Coyote Percolation Pond and Metcalf ponds (URS 2020b ~~2020c~~), and thus would experience less of an impact (i.e., less than moderate physiological stress). Juvenile spring downstream migrants are anticipated to experience only minor physiological stress for a short duration during migration.

During the wet season in Years 3, 4, 5, 6, and 7, the reservoir would be allowed to fill back up to Deadpool elevation and the Stage 2 diversion would be used to maintain the reservoir at that elevation. During constant inflow conditions, migrating adult Pacific lamprey could experience minor to moderate physiological stress (Appendix F ~~G~~) during constant inflows and precipitation events. If temporary, minor to moderate physiological stress usually has negligible long-term impacts on an animal and are often seen as adaptive responses that allow an animal to cope with a stressful event (Sapolsky 2021 ~~2004~~). However, minor to moderate physiological stress across long durations can result in sublethal impacts like impaired reproduction and increased susceptibility to disease and parasites. Pacific lamprey could behaviorally regulate their exposure and choose not to enter and migrate up Coyote Creek, potentially migrating up a different watershed to reproduce or they may continue to migrate up Coyote Creek and attempt to reproduce there. Pacific lamprey do not home to natal rivers (Spice et al. 2012) so there would likely be little consequence if migrating adults select another watershed for migration during Project construction. Also, Pacific lamprey die after spawning and are already experiencing high physiological stress as their bodies prepare to mate, spawn, and die so slight increases in physiological stress during their final migration would have a negligible impact on migrating adult lamprey.

Pacific lamprey larvae rear for a variable number of years before outmigrating to the ocean (Stillwater 2014); therefore, suspended sediment resulting from the Project could impact multiple year-classes of the population ~~(**Figure 3.4-2**).~~ Lamprey are reported to have an intermediate level of tolerance to increased sedimentation and turbidity (Zaroban et al. 1999), but it is not known how changes in suspended sediment affect larva survival. Pacific lamprey larvae can rear in burrows in fine sediment (Stillwater 2014), so they presumably tolerate spikes in suspended sediment to some extent, although excessive sedimentation from the settling out of suspended sediment could possibly smother larvae in some areas. Larvae are filter-feeders (Stillwater 2014), so reduced growth rates might be expected from elevated suspended sediment. However, the broad spatial distribution of Pacific lamprey in the Coyote Creek Watershed, including Upper Penitencia Creek, should mean that a large portion of the rearing larva population in the watershed would not be impacted by sediments during construction phase hydrology for the Project.

Little is known about Pacific lamprey eggs, but assuming eggs are not more sensitive than steelhead eggs then, conservatively, they could experience 0 to 20 percent mortality.

During 2-year to 5-year precipitation events, higher than usual flow events could lead to increased pool depths, reduced spawning gravel quantities, and reduced access to low-terrace floodplain habitat from increased channel incision in Coyote Creek (mainly upstream of Coyote Percolation Pond). Lower quality spawning habitat may reduce the survival of incubating eggs within these limited areas but over the long term, the increased and enhanced habitat from maintenance of the Live Oak Restoration Project; and the construction, operation, and maintenance of the Ogier Ponds CM would reverse impacts on Pacific lamprey habitat that occur in the wet seasons of construction and overall impacts on the population over time would not be substantial, particularly because Pacific lamprey are one population on the west coast of North America and do not have distinct populations in specific watersheds.

Although sediment transport would impact spawning habitat, the habitat impacted will primarily occur in the reaches upstream of Coyote Percolation Pond as a majority of sediment ~~a~~ deposits in the Ogier and Coyote Percolation ponds as described further in Appendix D ~~G~~. In addition, during seismic retrofit construction, Valley Water would conduct sediment deposition monitoring (Stillwater Sciences 2020b) annually and maintain spawning gravels ~~and augment sediment~~ per the Live Oak Restoration Project maintenance. In addition, post-construction monitoring and maintenance of Live Oak Restoration Project and Ogier Ponds CM, and implementation of the Sediment Augmentation Program, will continue long-term resulting in a net benefit for Pacific lamprey spawning habitat. ~~North Channel Extension Conservation Measures will also help protect spawning habitat in the southern channel, enhanced during FOCP, from high flow events.~~

In spring of Years 3, 4, 5, and 6, drawing the reservoir down to elevation 450 feet would occur with the Stage 2 diversion allowing up to 6,000 ~~1,000~~ cfs to pass directly through to downstream. Storm events are less likely in April and become less likely thereafter, but smaller storm events can occur, and the modeling simulated a 2-year storm event in addition to constant inflow in the absence of a storm event. Under constant inflow as well as the storm events, migrating or pre-spawning holding adults could experience minor to moderate physiological stress from elevated sediment transport (Appendix F ~~G~~) would be sublethal and temporary and may have no effect on the fitness of a species that dies after spawning as described above.

Outmigrating juveniles could experience minor to moderate physiological stress from elevated sediment transport under both constant inflow and storm event conditions. Spring downstream migrants are anticipated to only experience moderate physiological stress for a short duration during migration and impacts would not be substantial as the species is more tolerant of suspended sediment. Also, outmigrating juveniles are often found in turbid waters and may benefit from decreased predation pressure associated with higher turbidity. Juveniles often migrate with high-flow events (Ebert 2008, Richards and Beamish 1981, Close et al. 1995, van de Wetering 1998) so the spring drawdown may encourage them to migrate under cover of turbidity which may increase survival.

Little is known about Pacific lamprey eggs, but assuming eggs are not more sensitive than steelhead eggs then, conservatively, they could experience up to 20 percent mortality. Collectively, increased suspended sediment under constant flow and storm events during spring drawdowns would decrease productivity of the Pacific lamprey population during Years 3, 4, 5, and 6 of Project as compared to Pre-FERC Order Baseline, but changes from existing conditions baseline are likely negligible.

Following Year 6, the reservoir would be allowed to refill via inflows and, if possible, imported water up to the new maximum level and the FAHCE rule curves would be initiated. With the reservoir refilled, suspended sediment would decrease during constant inflow or precipitation events because the full reservoir would not have exposed erodible sediment at the same level as at the existing conditions baseline and suspended sediment would return to near Pre-FERC Order Baseline and would not be expected to impact Pacific lamprey further.

Overall, sediment transport in instream flows during Seismic Retrofit construction could result in periodic, temporary less than significant impacts to Pacific lamprey in the short-term (during the construction phase) during and immediately following wet season precipitation events and during the spring reservoir drawdowns during Seismic Retrofit construction. Suspended sediment monitoring, sediment deposition monitoring, the gravel and sediment augmentation programs, and the Ogier Ponds CM would prevent the long-term degradation of spawning habitat and would reverse the spawning and productivity impacts, resulting in less than significant impacts, and a net benefit to the Pacific lamprey population and its habitat in the long-term.

Non-native Species

Some aquatic non-native species likely prey on Pacific lamprey but for the same reasons outlined for steelhead, impacts from the release of non-native species from Anderson Reservoir downstream would not be significant compared to baseline conditions. The assemblage or distribution of non-native fish species in Coyote Creek is not expected to change. Changes associated with the project will not provide habitat that is more suitable. Actions taken by Valley Water during sampling activities and construction related dewatering will help reduce the abundance of non-native species.

Instream Flows During Construction Summary

Overall, construction phase dam operations and instream flows would maintain Pacific lamprey throughout the entire construction phase of the Project by providing flows, temperatures, and DO within a range that can maintain Pacific lamprey in the FCWMZ. Also, flows bypassed through the reservoir would be within a range that can support Pacific lamprey migration, spawning, incubation, and rearing in the FCWMZ during Seismic Retrofit construction. Dewatering in spring would encourage any remaining outmigrating juveniles. Sediment transport would be the main impact from instream flows during construction causing sublethal physiological stress in adults and juveniles and some (0-20 percent) mortality of incubating eggs which would in turn decrease productivity of the Pacific lamprey population during construction compared with the Existing Conditions Baseline but sediment deposition would be monitored throughout the Project and impacts would be reversed through Ogier Pond Restoration, sediment augmentation and Live Oak Restoration Reach maintenance programs, which would enhance spawning habitat and support higher productivity for the Pacific lamprey population into the future during and following construction. Therefore, overall, the impacts from instream flows during construction would be less than significant for the Pacific lamprey population and its habitat. Pacific lamprey would benefit from the seismic retrofit construction over the long term because the seismically retrofitted dam would have more flexibility in managing cold water releases.

Conservation Measures Construction Impacts Analysis

The following Conservation Measures, Normal Operation of Coyote Reservoir and Construction Period Imported Water Releases and Operation of the Chillers for Imported Water Releases, do not have a construction component and were previously considered as part of the *Instream Flows during Seismic Retrofit Construction* under the *Seismic Retrofit Construction Activities Impacts Analysis,* so they are not discussed further in this section.

Construction activities for the Conservation Measures that require construction are considered in this section. Conservation Measure construction could impact Pacific lamprey in the short-term but would likely benefit Pacific lamprey in the long-term. Conservation Measure construction components that could impact Pacific lamprey are assessed in further detail in this section.

Ogier Ponds Conservation Measure Project

Even though the goals and objectives of the Ogier Ponds CM are aimed at steelhead, there would be overlap with improvements to rearing habitat for both species. This Conservation Measure would benefit Pacific lamprey through increased rearing habitat, improved water quality (i.e., lower water temperature), enhanced fish passage, riparian habitat restoration, and reduced habitat for warm water, non-native fish, particularly that of predatory species, in the system.

While the Ogier Ponds CM would provide substantial benefits to Pacific lamprey once complete, construction activities to complete the conservation measure would have short-term impacts. The in channel work window precludes in-channel construction activities during a majority of the juvenile downstream migration. Pre-spawning holding, spawning, larval rearing, and, although unlikely, adult upstream migrating Pacific lamprey may be present during the work window; therefore, Ogier Ponds CM construction activity impacts during the work window are analyzed for adult upstream migration, holding, spawning, and rearing Pacific lamprey while no impacts are expected for juvenile emigrants. During the wet season, fish passage would be provided which would minimize migration impacts to Pacific lamprey. Adult Pacific lamprey have been documented migrating, as late as June 30 so there may be some impact on migration at the very end of the migration season. However, typical flows that provide for migration occur much earlier in the season in the county so impacts to migration would be unlikely in the 2-week window from June 15-June 30 at the beginning of the construction window.

Construction activities and localized dewatering during construction would have similar impacts on Pacific lamprey as described for steelhead. Pacific lamprey adults, juveniles, redds, and larvae have the potential to become desiccated or suffocate during dewatering or may be crushed during construction activities. While buried in sediment, larvae can be difficult to salvage if present, and may not move out of construction areas on their own volition. However, lamprey larvae have been shown to withstand prolonged periods of dewatering if they can burrow deep enough in the hyporheic zone to remain wetted (Rodriguez-Lozano et al. 2019), making them more resilient to dewatering than salmonids. There is minimal spawning habitat present downstream of the CWMZ, which would limit redds within or downstream of the construction footprint.

The Aquatic Species Rescue and Relocation Plan for the Ogier Ponds CM would reduce impacts of fish stranding during dewatering by implementing a fish rescue and relocation effort during localized dewatering. Capture methods would include backpack electrofishing, seining, dip netting, and/or capturing by hand adopting measures from the Best Management Guidelines for Native Lampreys During In-water Work (Lamprey Technical Workgroup 2020).

In the short-term, impacts on Pacific lamprey would be less than significant. Actions are taken through ~~I~~AMMs and BMPs to reduce potential impacts. Over the long-term, Pacific lamprey would benefit from increased rearing habitat, improved water quality, enhanced fish passage, and decreased habitat for warm water, non-native predatory fish in the system.

Maintenance of the North Channel Reach ~~*North Channel Extension*~~

~~Construction~~ Maintenance activities associated with the North Channel Reach ~~Extension~~ would occur during Project construction ~~the dry season work window of Construction Year 1 as defined in *Section 2.5.1.1 Schedule* and BMP BI-2. The Conservation Measure activities~~ and include localized dewatering and minor grading in the channel.

If there is water in the North Channel and Pacific lamprey ~~or redds~~ are present, localized dewatering during construction activities could strand Pacific lamprey individuals ~~or redds~~ or trap them in pools, subjecting them to increased predation pressure or water quality degradation.

~~Construction~~ Maintenance activities and localized dewatering during maintenance ~~construction~~ would have similar impacts on Pacific lamprey as described for steelhead. Pacific lamprey individuals have the potential to become desiccated or suffocate during dewatering or may be injured, crushed, or killed during maintenance ~~construction~~ activities. While buried in sediment, larvae can be difficult to salvage if present, and may not move ~~out of construction areas~~ on their own volition.

Impacts to Pacific lamprey from this Conservation Measure would be avoided through defined work windows and measures implemented to protect ~~aquatic~~ fish, as discussed in the steelhead impacts section. The dry season work window precludes in-channel maintenance ~~construction~~ activities during juvenile downstream migration and begins during the final weeks of the adult upstream migration period. Pre-spawning holding, spawning, larval rearing, and adult upstream migrating Pacific lamprey may be present during the dry season work window. However, as the Project footprint for construction is immediately downstream of Anderson Dam, there would be no impacts on adult upstream migrants as there is no habitat available for Pacific lamprey upstream of the Project footprint.

~~In addition, Pacific lamprey would be excluded with nets and a cofferdam would be built at the lower limit of the backwater to keep water from entering the work area. The Aquatic Species Rescue and Relocation Plan for the North Channel Extension would reduce impacts of fish stranding during dewatering by implementing a fish rescue and relocation effort adopting measures from the Best Management Guidelines (Lamprey Technical Workgroup 2020) for Native Lampreys, where any remaining Pacific lamprey in the upstream pool would be captured and relocated prior to and during dewatering the pool.~~

~~In the short term, impacts~~ Impacts on Pacific lamprey would be less than significant with implementation of BMPs and AMMs. Over the long term, Pacific lamprey would benefit from protection of enhanced habitat in the South Channel via maintenance of high flow conveyance in the North Channel. ~~reduced stranding and predation in the existing North Channel pools when they dewater following activation.~~

Maintenance of Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach

At the end of FOCP (existing conditions baseline), the Live Oak Restoration Reach project will be completed, providing new and enhanced spawning and rearing habitat for Pacific lamprey. The restoration maintenance of that reach is proposed as a part of Project and would have a long-term benefit for Pacific lamprey by maintaining spawning habitat that was enhanced during FOCP. To maintain spawning habitats, the extent of spawning gravels to replenish would be assessed during visual observations and following monitoring surveys. Inferential and calculated volumes for spawning gravel volumes would be used to evaluate the need for replenishment of spawning gravel volumes. Stockpiled spawning gravel would be added in small increments to maintain spawning habitat.

Placement of gravels has the potential to degrade water quality downstream of the work area if gravels and associated fine sediment enter the stream at the time of placement, which could impact rearing and pre-spawning holding adult Pacific lamprey. However, gravels would be thoroughly washed of fine sediment prior to placement and silt curtains with a belting conveyor would be used to place the gravels limiting impacts to aquatic and riparian areas. ~~gravels will be placed during the dry seasons work window, and will not be placed directly in the channel, but instead will be placed adjacent to the channel or on benches above the channel so there would be no impact from introducing gravels to the channel at the time of placement. Also, when flows are high enough to mobilize the gravels in the gravel augmentation piles, there would already be elevated background levels of suspended sediment; therefore, additional sediment from the gravel piles would not add substantially to the total sediment that is already suspended during high flows.~~

~~Measures would be implemented to protect aquatic fish in the unlikely event that gravels and associated fine sediment enters the stream at the time of placement, as discussed in the steelhead impacts section. In addition, impacts~~ Impacts on Pacific lamprey from this Conservation Measure would be the same as for steelhead and avoided and minimized through defined work windows. The dry season work window precludes in-channel construction activities during juvenile downstream migration and begins during the final weeks of the adult upstream migration period. Pre-spawning holding, spawning, larval rearing, and adult upstream migrating Pacific lamprey may be present during the dry season work window. In addition, the methods described in the Best Management Guidelines for Native Lampreys During In-water Work (Lamprey Technical Workgroup 2020) would be implemented during the construction phase, if feasible.

In the short-term, impacts on Pacific lamprey would be less than significant from placing gravel. Over the long term, Pacific lamprey would benefit from maintaining spawning habitat within the Live Oak Restoration Reach.

Sediment Augmentation Program

The Sediment Augmentation Program would improve geomorphic processes that create and maintain spawning habitat and reduce and reverse channel incision, benefiting Pacific lamprey in Coyote Creek. Placement of sediment has the potential to degrade water quality downstream of the work area if sediment enters the stream at the time of placement, which could impact Pacific lamprey. A small rise in suspended sediment could occur when sediment is mobilized during high-flow events which may cause acute physiological stress and impeded foraging ability in Pacific lamprey. However, the increased turbidity and any associated stress and impeded foraging would resolve quickly (less than 8 hours) and would not adversely impact Pacific lamprey in the long term. Furthermore, when flows are high enough to mobilize the sediment in the sediment augmentation piles there would already be elevated background levels of suspended sediment; therefore, additional sediment from the piles would not add substantially to the total sediment that is already suspended during high flows.

Measures would be implemented to protect fish in the unlikely event that gravels and associated fine sediment enters the stream at the time of placement, as discussed in the steelhead impacts section. In addition, impacts on Pacific lamprey from this Conservation Measure would be avoided through defined work windows. The BMP GEN-1 work window for maintenance precludes in-channel construction activities during juvenile downstream migration and begins during the final weeks of the adult upstream migration period. Pre-spawning holding, spawning, larval rearing, and adult upstream migrating Pacific lamprey may be present during the in-channel work window for maintenance defined under BMP GEN-1.

Disturbance or injury impacts and measures to protect Pacific lamprey would be the same as described for steelhead. In the short term, impacts on Pacific lamprey from placing sediment and gravels would be less than significant. Over the long term, Pacific lamprey would benefit from improved geomorphic processes that create and maintain spawning habitat in the CWMZ and reduce <u>and reverse</u> channel incision.

Phase 2 Coyote Percolation Dam Fish Passage Enhancements

While the Phase 2 Coyote Percolation Dam CM would benefit Pacific lamprey once complete, construction activities to complete the conservation measure could have short-term impacts. Construction of this conservation measure requires localized dewatering. Pacific lamprey have the potential to become desiccated or suffocate during dewatering or may be injured, crushed, or killed during construction activities.

Construction activities and localized dewatering during construction would have similar impacts on Pacific lamprey as described for steelhead. While buried in sediment, larvae can be difficult to salvage if present, and may not move out of construction areas on their own volition. However, lamprey larvae have been shown to withstand prolonged periods of dewatering if they can burrow deep enough in the hyporheic zone to remain wetted (Rodriguez-Lozano et al. 2019), making them more robust to dewatering than salmonids.

Due to high water temperatures during the dry season work window, Pacific lamprey are not anticipated to be present in the Phase 2 Coyote Percolation Dam CM construction area during the period of disturbance. However, measures would be implemented to protect any Pacific lamprey that are present, as discussed in the steelhead impacts section, and would protect Pacific lamprey from being injured or killed during dewatering activities and sediment impacts.

BMP BI-2 will protect Pacific lamprey from stranding during dewatering and impacts from increased suspended sediment in the channel by restricting in-channel construction activities to the dry season work window. The work window precludes in-channel construction activities during juvenile downstream migration and begins during the final two weeks of the adult upstream migration period. Pre-spawning holding, spawning, larval rearing, and adult upstream migrating Pacific lamprey may be present during the work window. There is minimal spawning habitat present downstream of the CWMZ, which would limit redds within or downstream of the construction footprint. In addition, the methods described in the Best Management Guidelines for Native Lampreys During In-water Work (Lamprey Technical Workgroup 2020) would also be implemented during the construction phase, if feasible. During the wet season, fish passage would be provided which would minimize migration impacts to Pacific lamprey. Adult Pacific lamprey have been documented migrating as late as June 30 so there may be some impact to migration at the very end of the migration season. However, typical flows that provide for migration occur much earlier in the season in the county so impacts to migration would be unlikely in the 2-week window from June 15-June 30 at the beginning of the construction window.

In the short-term, impacts on Pacific lamprey would be less than significant with implementation of applicable BMPs, AMM's and PAMMs. Over the long-term, Pacific lamprey would benefit from the Coyote Percolation Dam CM through improved passage conditions.

Construction Monitoring Impacts Analysis

Construction Phase Fisheries Monitoring

Fisheries and habitat monitoring would provide valuable information to inform management of steelhead and other fish species in the study area and guide Valley Water and regulatory agencies in decision making regarding the Fish Rescue and Relocation Plan. Water quality ~~temperature~~ monitoring, suspended sediment monitoring, VAKI Riverwatcher adult escapement monitoring, spawning surveys, sediment deposition, eDNA, ~~and~~ migration flow monitoring, PIT tag migration study, growth comparative study, non-native control methods, reptile monitoring, and terrestrial animal monitoring ~~are all non-invasive monitoring methods that~~ would have no impacts on Pacific lamprey. Sensitive Habitat Monitoring and Groundwater Monitoring would not adversely impact Pacific lamprey as these studies do not require in-channel sampling. Groundwater monitoring would not adversely impact Pacific lamprey because monitoring wells are located outside the active channel of Coyote Creek.

~~Pacific lamprey may be unintentionally captured during Fyke Trapping activities, though this is very rare due to the position in the watershed (out flow of Anderson Dam). Capturing and handling Pacific lamprey could cause acute physiological stress. Injury and mortality are rare but happen occasionally. Valley Water would be subject to the terms and conditions of California Scientific Collecting Permits which include impact avoidance and minimization measures during these studies.~~

~~A majority of the monitoring activities will not result in any impacts to Pacific Lamprey or their habitat as they are non-invasive. Any monitoring that~~ Juvenile rearing studies for steelhead could result in capture of Pacific lamprey but have ~~has~~ a low potential of actually handling this species. Therefore, there would be ~~no impact~~ less than significant impacts on Pacific lamprey from Construction Monitoring.

Construction Phase Fish Rescue and Relocation; Juvenile Rearing, Migration, and Growth

If monitoring of water temperature and DO indicates that conditions for rearing steelhead would become unsuitable within the Coyote Creek FCWMZ as a result of Seismic Retrofit construction activities, steelhead would be rescued and relocated per the Fish Rescue and Relocation Plan. Capture methods would include backpack electrofishing and/or seining. Pacific lamprey captured during the rescue efforts would also be relocated per the Fish Rescue and Relocation Plan. Also, pacific lamprey may be captured during the juvenile rearing sampling which uses the same backpack electrofishing methods. Pacific lamprey may be stunned/netted, captured, and handled causing acute physiological stress. Injury or mortality can happen occasionally but are rare. Most Pacific lamprey tolerate capture and handling. Acute physiological stress would be temporary and less of a concern than mortality under deteriorating water quality conditions.

Invasive Species Monitoring and Control Plan

Impacts to and benefits to Pacific lamprey from implementing the Invasive Species Monitoring and Control Plan would be the same as outlined for steelhead. This plan would result in a reduction to potential predators to Pacific lamprey and would benefit the species in the short term.

Construction Monitoring Summary

Overall, construction monitoring would result in short-term less-than-significant impacts to Pacific lamprey.

Post-Construction Instream Flows Operations (FAHCE Rule Curves)

Analyses of the effects of the Project on Pacific lamprey, including spawning, rearing, and migration habitat in Coyote Creek, are provided in the following subsections. There were no WEAP Model outputs for Pacific lamprey. Thus, the effects of the Project on Pacific lamprey habitat and passage were evaluated using other modeled data, including water temperature, wetted area and thalweg depth, and WEAP Model results for steelhead when life stage timing and habitat preference overlap between the species (Appendix F).

Spawning and Incubation Habitat

The Project is predicted to result in an increase in Pacific lamprey spawning and incubation habitat compared with the Future Baseline, with a predicted decrease in spawning and incubation habitat relative to the Pre-FERC Order baseline. This determination is based largely on the WEAP model results for steelhead, which rely on suitability criteria for water depth, water velocity, spawning gravel characteristics, and water temperature that correspond closely with those for Pacific lamprey (Appendix F). This decrease is based on factors that are not related to implementation of the Project or proposed FAHCE rule curves (e.g., changes in conservation, water supply demand resulting in less imported water released into Coyote Creek), and the decrease is predicted to occur without implementation of the Project. Comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order Baseline because both the Project and Future Baseline scenarios represent conditions occurring at the same point in time (i.e., 2035) and both are based on the same assumptions regarding water conservation, water supply and demand, climate change, and other factors affecting flows and habitat in Coyote Creek. Accordingly, the Project would to benefit spawning Pacific lamprey.

The steelhead WEAP model results are considered conservative estimates (i.e., underestimates) of spawning and incubation habitat for Pacific lamprey because Pacific lamprey have a greater range of water temperature suitability than steelhead. While the March–August Pacific lamprey spawning and incubation period occurs later in spring and summer compared with the December–April steelhead spawning and incubation period used in the WEAP model, analysis of modeled water temperature in Coyote Creek indicates that daily average water temperature under the Project would be suitable for Pacific lamprey spawning and incubation (50–71 °F) at all locations in Coyote Creek during the entirety of the spawning and incubation period (Appendix F). The WEAP model predictions of steelhead incubation adjusted spawning habitat are therefore considered underestimates of suitable Pacific lamprey spawning and incubation habitat.

In addition to the modeled changes in spawning habitat under the Project, the Ogier Ponds CM and the Sediment Augmentation Program that will rely on increased flows from the North Channel Extension Project (completed during FOCP) would create and enhance a substantial amount of spawning habitat. The Ogier Ponds CM Project would add over 20,000 square feet of spawning habitat at typical winter baseflow (approximately 30 cfs). This spawning habitat estimate is based on steelhead criteria but is also expected to be usable by Pacific lamprey.

Furthermore, implementation of the Ogier Ponds CM would improve spawning suitability downstream of Ogier Ponds by disconnecting the creek from the ponds and eliminating the introduction of warmed water from the ponds to Coyote Creek, thereby reducing water temperatures in the restored creek channel downstream of Ogier Ponds during warmer months (Valley Water 2023b ~~2023c~~). While spawning Pacific lamprey have a higher water temperature tolerance than steelhead, the reduced water temperatures would somewhat improve spawning suitability for Pacific lamprey as well. The Sediment Augmentation Program would create additional spawning habitat that would be usable by Pacific lamprey. Therefore, implementation of the FAHCE rule curves in combination with the Ogier Ponds CM, the Sediment Augmentation Program, and the increased flows conveyed through the maintained North Channel ~~Extension~~ would contribute to additional increases in Pacific lamprey production potential in Coyote Creek downstream of Anderson Dam.

Overall, the amount of spawning and incubation habitat under the Project would increase substantially compared to Pre-FERC Order Baseline with implementation of the FAHCE rule curves in the context of the restored and enhanced habitat under the aforementioned Conservation Measures, with overall benefits to Pacific lamprey.

Larval and Juvenile Rearing

The Project is predicted to slightly increase larval and juvenile rearing habitat for Pacific lamprey in Coyote Creek downstream of the dam compared with the Future Baseline. Rearing habitat for Pacific lamprey would decrease slightly compared with the Pre-FERC Order Baseline. This determination is primarily based on the wetted area predictions of the WEAP Model, with additional consideration of habitat restored and enhanced via Conservation Measures and modeled water temperatures during the year-round Pacific lamprey rearing period.

While water temperature tolerances of Pacific lamprey larvae and juveniles are not well understood, the limited available information suggests that suitable rearing temperatures correspond closely to the water temperatures used in the WEAP model to define the optimal growth range (50–65 °F) and survivable water temperatures (36–75 °F) for steelhead fry and juveniles. However, larval Pacific lamprey have been found where water temperatures are 75 °F or greater (*Section 3.4.2, Environmental Setting, Pacific Lamprey*, and Appendix F). Suitable rearing substrates differ considerably between the species, with Pacific lamprey larvae and juveniles requiring fine substrates (e.g., silt) along channel margins, in backwaters, and in other slow-water areas during their 4-8-year larval phase. Pacific lamprey larvae can withstand prolonged periods of dewatering if they can burrow deep enough in the fine substrate to remain wetted, making them more resilient to decreases in wetted area than steelhead.

With implementation of the FAHCE rule curves, flows under the Project would have spatially and temporally variable effects on wetted area in Coyote Creek compared with Pre-FERC Order Baseline and Future Baseline conditions. Average water temperatures during the warmest summer months would decrease at all locations in Coyote Creek under the Project compared with the Pre-FERC Order Baseline and Future Baseline. Although modeled average and daily maximum water temperatures at most locations under Pre-FERC Order Baseline and Future Baseline conditions are not predicted to exceed the presumed temperature tolerance of rearing Pacific lamprey larvae and juveniles (Appendix F), the reduced summer water temperatures as compared to both baselines would improve rearing conditions for Pacific lamprey during this portion of their year-round rearing period.

Compared with the Pre-FERC Order Baseline, the Project would result in decreased wetted area and lamprey rearing habitat in March and April at all locations because of reduced flows and would have variable effects on wetted area from December through February. Decreases or no change in wetted area and lamprey rearing habitat would occur in Coyote Creek from May through October as a result of slight, variable reductions in summer base flow and wetted area at most locations, with an increase in wetted area occurring only at POI COYO 10 during this period.

Compared with the Future Baseline, the WEAP Model results suggest the Project would have no effect or would slightly increase the amount of Pacific lamprey rearing habitat from December through April because of increased wetted area. The Project would have variable effects on rearing habitat availability and suitability during the summer and fall resulting from reduced wetted area for rearing but beneficial reductions in water temperature compared with the Future Baseline. Based on the results of the WEAP Model, the Project would have negligible effects on wetted area at POIs COYO 1–3 year-round and thus no appreciable changes to Pacific lamprey rearing habitat compared with the Future Baseline. At POIs COYO 4–9, increases or no change to wetted area would occur from December through April, and decreases to wetted area would occur at most of these locations from May through November. At POI COYO 10, small increases to wetted area and lamprey rearing habitat would occur from January through April, with substantial increases occurring from May through October compared with the Future Baseline. In November and December at POI COYO 10, the Project would result in decreases to wetted area and Pacific lamprey rearing habitat compared with the Future Baseline. As described previously, comparison with the Future Baseline provides a more accurate depiction of Project benefits than comparison with the Pre-FERC Order Baseline. Accordingly, effects of the Project on Pacific lamprey larval and juvenile rearing habitat are evaluated primarily by comparison with the Future Baseline. While the effects of the Project are predicted to be spatially and temporally variable, the Project would provide marginal benefits to rearing Pacific lamprey larvae and juveniles.

The Ogier Ponds CM would increase the amount of main channel habitat and improve river-riparian function in the restoration area, thereby enhancing natural sediment deposition processes that would ~~likely~~ provide localized areas of suitable rearing habitat for Pacific lamprey in combination with the FAHCE rule curves. By separating the ponds from the creek and restoring riverine function, the Ogier Ponds CM would also reduce spring, summer, and fall water temperatures in Coyote Creek downstream of the Ogier restoration area, thus improving rearing habitat suitability for Pacific lamprey downstream of Ogier Ponds. However, there is potential larval rearing habitat in Ogier Ponds under the Pre-FERC Order Baseline, which may be lost after construction of the Ogier Ponds CM in exchange for in channel habitat.

Overall, wetted area in Coyote Creek would be increased during winter and spring but reduced during summer and fall under the Project in comparison with the Future Baseline, resulting in little or no change to the amount of Pacific lamprey rearing habitat on an annual basis.

Adult Upstream Passage and Pre-Spawning Holding

During the adult Pacific lamprey upstream migration period (January 1–June 30), the WEAP Model results for thalweg depth indicate an average decrease of 5 days per year in modeled adult upstream passage opportunities in Coyote Creek under the Project compared with the Pre-FERC Order Baseline and the Future Baseline. Reductions in modeled daily average water temperature at all locations under the Project during the adult upstream migration period, and most substantially during May and June (Appendix F), would increase suitability for upstream passage by adult Pacific lamprey compared with the Pre-FERC Order Baseline and the Future Baseline. Considering both the slight reduction in passage days due to changes in thalweg depth and the increase in passage suitability due to reduced water temperature, the Project would have no effect on adult Pacific lamprey passage opportunities compared with both the Pre-FERC Order Baseline and the Future Baseline.

The pre-spawning holding stage begins when individuals cease upstream movement, generally in early summer, and continues until fish begin their secondary migration to spawn the following spring.

Based on the results of the WEAP Model, the Project would result in variable changes to pre-spawning holding habitat compared with the Pre-FERC Order Baseline, depending on the month and location within Coyote Creek. Reductions in modeled daily average water temperature at all locations under the Project, and most substantially during May and June (Appendix F), would increase suitability for pre-spawning holding by adult Pacific lamprey compared with the Pre-FERC Order Baseline and the Future Baseline. Although the WEAP Model predicts reductions in wetted area in summer at POIs COYO 4–9 under the Project compared with both the Pre-FERC Order Baseline and the Future Baseline, the reduction in daily average water temperature during this time provides cooler summer water temperatures that reduce the likelihood that the 68 °F (20 °C) optimal pre-spawning holding temperature threshold would be exceeded during this period. Although not considered in the WEAP water temperature modeling, the expected reduction in summer and fall water temperatures downstream of the Ogier Ponds restoration area following completion of the Ogier Ponds CM would also contribute to increased suitability for pre-spawning holding Pacific lamprey downstream of POI COYO 8. Despite the effects of reduced wetted area under the Project, the improvements in water temperature suitability for pre-spawning holding during summer would benefit adult Pacific lamprey pre-spawning holding compared with both the Pre-FERC Order Baseline and the Future Baseline.

Juvenile Downstream Passage

During the juvenile Pacific lamprey downstream migration period (December 1–May 31), the WEAP Model results for thalweg water depth indicate no change on average to downstream migration opportunities under the Project compared with the Pre-FERC Order Baseline and the Future Baseline. Based on these model results, and because outmigration by juvenile Pacific lamprey typically occurs during winter and spring high-flow events when water depth and water temperature are suitable, the Project would have no effect on juvenile Pacific lamprey downstream passage.

Post-Construction Instream Flows (FAHCE Rule Curves) Summary

Compared with the Future Baseline, the post-construction Anderson Dam and instream flows operations under the Project would have little or no adverse impacts on the Pacific lamprey population in Coyote Creek, with likely benefits to production. Compared with the Pre-FERC Order Baseline, the Project would slightly reduce juvenile rearing habitat for Pacific lamprey but, as previously described, comparisons with the Pre-FERC Order Baseline do not represent Project benefits as accurately as comparisons with the Future Baseline. Overall, The post-construction instream flows would benefit Pacific lamprey and have no impact on their population with regard to adverse impacts.

Post-Construction Seismic Retrofit and Conservation Measures Operations, Maintenance, and Adaptive Management

All post-construction monitoring and maintenance activities that were previously described in the steelhead and Chinook salmon equivalent sections that were covered by the DMP, SMP, and PMP also apply to the Pacific lamprey analysis and are not repeated here. Operational impacts or benefits specific to Pacific lamprey are discussed further in this section.

Anderson Dam Post-Construction Operations

Pacific lamprey would have the same short-term less than significant impacts from maintenance and monitoring and the same long-term benefits from more flexible operations of Anderson Dam as were described for steelhead. This includes operational flexibility that would benefit Pacific lamprey by allowing Valley Water to meet FAHCE temperature requirements for instream flows downstream of the dam. All maintenance is covered under the DMP, SMP, and PMP which are covered under additional permits. These improvements and programs would support a larger and more resilient Pacific lamprey population.

Ogier Ponds Conservation Measure Operations

The restored channel created via the Ogier Ponds Conservation Measure will operate and function as a natural creek channel. Weirs will be activated infrequently when flow levels reach 2000 cfs, and will be spillover, not requiring any actions. Pacific lamprey would have the same short-term less than significant impacts from maintenance and monitoring and the same benefits from a restored channel habitat as were described for steelhead. These improvements would support a larger and more resilient Pacific lamprey population.

North Channel Reach Maintenance and Monitoring ~~Extension Operations~~

Pacific lamprey would have the same short-term less-than-significant impacts from maintenance and monitoring and the same benefits ~~from enhanced passage of geomorphic flows and decreased stranding risk~~ as were described for steelhead. The operations of the North Channel will be monitored by the SMP and will be maintained to provide the benefits associated with reduced stranding and passage of geomorphic flows. These maintained improvements would support a larger and more resilient Pacific lamprey population.

Spawning Gravel and Rearing Habitat Enhancements in the Live Oak Restoration Reach ~~and Sediment Augmentation Program~~

Even though the goals and objectives of the spawning gravel and habitat enhancements in the Live Oak Restoration Reach ~~and Sediment Augmentation Program~~ are aimed at steelhead, there would be overlap with the gravel sizes Pacific lamprey need for spawning. This Program would improve spawning substrate and geomorphic processes within the CWMZ and reduce and reverse channel incision, benefiting Pacific lamprey their habitat. Maintenance would include placing gravel which would be covered under the SMP and its extensive BMPS, Pacific lamprey would have the same short-term less than significant impacts from maintenance and monitoring and the same benefits from long-term maintenance of spawning gravels and rearing habitat enhancements. Combined, these improvements would support a larger and more resilient Pacific lamprey population.

Sediment Augmentation Program

Even though the goals and objectives of the Sediment Augmentation Program are aimed at steelhead, the general improvement in geomorphic processes in Coyote Creek would benefit Pacific lamprey. This Program would improve geomorphic processes within the CWMZ and reduce and reverse channel incision, benefiting Pacific lamprey and their habitat. Maintenance would include placing sediment which would be covered under the SMP and its extensive BMPs, Pacific lamprey would have the same short-term less than significant impacts from maintenance and monitoring and the same benefits from long-term maintenance of the Sediment Augmentation Program. Combined, these improvements would support a larger and more resilient Pacific lamprey population.

Phase 2 Coyote Percolation Dam CM Operations

Operations of the Coyote Percolation Dam will provide safe, effective, and timely upstream and downstream passage of anadromous fish, including Pacific lamprey. Pacific lamprey would have the same short-term less-than-significant impacts from maintenance and monitoring and some of the same benefits from enhanced migration conditions from Coyote Percolation Dam operations as described for steelhead. These improvements would support a larger and more resilient Pacific lamprey.

Project and FAHCE Adaptive Management

As discussed for steelhead and Chinook salmon, refinements under the AMP would likely have impacts similar to those discussed in this EIR under Conservation Measures Construction but at a much smaller scale for Ogier Ponds CM and the Phase 2 Coyote Perc Dam. Similarly, adaptive management of the Sediment Augmentation Program and Live Oak Restoration Reach ongoing maintenance would have short-term impacts similar to those described for placement and ongoing, periodic maintenance of gravels. Therefore, some short-term impacts would be predicted if there are any construction components to the adaptive management of Conservation Measures and long-term benefits from operation of these Conservation Measures would be predicted given that the AMP focuses on enhancing steelhead and Chinook salmon habitat and Pacific lamprey have a lot of overlap in habitat needs with steelhead.

Under the AMP, there would be compliance monitoring, validation monitoring, effectiveness monitoring, and a long-term trend monitoring program. Compliance and validation monitoring would collect data through passive monitoring technology and habitat surveys and would have no impact on Pacific lamprey. Long-term trend monitoring would include passive monitoring such as VAKI Riverwatchers or PIT antennas using noninvasive technology and would have no impact on Pacific lamprey.

Long-term monitoring would also include stunning through electrofishing, capturing/netting, crowding, handling, DNA sampling, and PIT tagging steelhead which may incidentally stun, capture/net, or crowd adult Pacific lamprey in their pre-spawning holding life history stage. These activities can cause acute physiological stress and occasional (but rare) incidental injury and/or mortality. Often electrofishing settings aimed at steelhead are not as effective at stunning and capturing Pacific lamprey larvae burrowed in fine sediment but there may still be some stunning of larvae during electrofishing monitoring. Electrofishing would follow standard NMFS and CDFW survey protocols, which would minimize injury and mortality of Pacific lamprey during stunning, capturing, handling, and sampling steelhead.

The monitoring program would provide valuable long-term individual and population information for steelhead and Chinook salmon that could be used to adjust components of the Project through the AMP to be more beneficial to steelhead and Chinook salmon over the long term. Any adaptive management measures that are implemented would probably benefit Pacific lamprey as well, given common habitat needs with the focal fish species. Also, information about Pacific lamprey would be collected incidentally while monitoring steelhead and Chinook salmon. There are still many information gaps about Pacific lamprey life history, behavior, habitat needs, as well as their population. Any new information would help inform future conservation management efforts aimed at Pacific lamprey by providing best available information. Therefore, the impacts of monitoring activities implemented under the AMP would not be substantial and may prove to be beneficial for Pacific lamprey.

The post-construction operations flow releases from Anderson Dam may be modified in a Geomorphic Flows Plan (Section 2.4, *Overview of Project Components*) to achieve geomorphic function of the river system via floodplain inundation, spawning gravel maintenance, and channel formation. Implementation of geomorphic flows in conjunction with the Sediment Augmentation Program (Section 2.6.3, *Sediment Augmentation Program*) would address historical blockage of sediment by Anderson Dam and Reservoir restoring more natural geomorphic processes downstream of the dam benefiting Pacific lamprey and their habitat.

Overall, the Project and FAHCE AMP would benefit Pacific lamprey. Any adaptive measures with a construction component would likely have less than significant impacts on steelhead and long-term benefits

Significance Conclusion Summary for Pacific Lamprey

The Project would result in certain impacts on Pacific lamprey from Seismic Retrofit Project Construction; Conservation Measures Construction; Construction Monitoring; Post-Construction Instream Flows Operations; and Anderson Dam and Conservation Measures Maintenance, and Adaptive Management. The Project would benefit Pacific lamprey and their habitat through Seismic Retrofit Project operation; Conservation Measures operation; Construction Monitoring; Post-Construction Instream Flows Operations, and the Project and FACHE AMP. Overall, impacts on Pacific lamprey would be **less than significant** in the short term. There would be long-term benefits to the Pacific lamprey population and habitat.

Mitigation Measures

No mitigation is required.

Impact FR-1d: Sacramento Hitch **(Less than Significant)**

Seismic Retrofit Construction

Seismic Retrofit Construction Activities

Sacramento hitch are found in the reservoir, as well as below the dam. Limited sampling has occurred upstream of Anderson Reservoir; however, Sacramento hitch have been captured in Coyote Reservoirs and during recent fyke net trapping efforts during Anderson Reservoir dewatering in Coyote Creek (Leidy 2007; Valley Water 2020c, 2021d ~~2021c~~). Anderson Reservoir Fyke Trapping in fall 2020 and spring 2021 sampled the fish potentially moving from the reservoir to Coyote Creek during reservoir drawdown. A total of 62 live and 2 dead Sacramento hitch were captured during the fyke trapping efforts, suggesting that a population may be present in Anderson Reservoir, but since there was over 30 meters of channel upstream of the fyke trap, it cannot be confirmed if the hitch actually came from the reservoir or were just using that portion of the channel. Some exploratory sampling with an electrofishing boat in 2023 did not detect Sacramento hitch in the reservoir but the sampling was limited in coverage so cannot confirm hitch absence under existing conditions baseline and hitch can be reseeded in the reservoir from upstream locations and Coyote reservoir (Valley Water 2023c ~~C. Leal Pers. comm. 2023~~). These results indicate that at least some Sacramento hitch present during reservoir dewatering may successfully pass downstream and occupy stream habitats downstream of Anderson Dam, where Sacramento hitch are present (Leidy 2007, Valley Water 2021a).

Seismic Retrofit construction activities could impact Sacramento hitch individuals or their habitat in the reservoir pool and from immediately downstream of the dam to Alviso Slough. Construction activities within the reservoir would include dewatering of the reservoir to elev. 450 ~~467~~ feet during Year 1, elev. 450 feet during Year 2, elev. 453 feet during Years 3, 4, 5, and 6; installation of a cofferdam with sheet pile cutoff wall and temporary sediment check dams; construction of the Stage 2 diversion system; excavation and reconstruction of the dam including raising the dam crest; interim dam winterization; construction of the outlet works; and spillway replacement. In addition to reservoir dewatering, Seismic Retrofit construction may require some other localized dewatering within the construction footprint in the reservoir.

In Year 5, blasting at the BHBA could directly impact Sacramento hitch in the Anderson Reservoir if present. Blasting would occur throughout Year 5 (11 months) and blasting noise and vibrations may cause acute physiological stress, changes in behavior (e.g., changing from foraging to hiding), and, in extreme cases, injury or death if the noise and vibrations are substantial, close by, and/or repeated. Blasting procedures would be developed by a qualified blaster to control noise, air-overpressure, ground vibration, flyrock, and dust. The contractor would be required to implement minimization measures to limit noise generated by blasting to 75 dBA or less towards residential receptors which would also minimize noise and vibrations for Sacramento hitch. All impacts from noise and vibration disturbance from blasting at the BHBA are anticipated to be sublethal and not substantial to the Sacramento hitch population.

Sacramento hitch are present in Coyote Creek in various life stages throughout the year. Sacramento hitch can spawn as early as February and as late as July, hatching typically occurs within a week, and then young Sacramento hitch spend about 2 months in shallow water or near aquatic plant beds before moving to open water. Sacramento hitch are not migratory and would be present in Coyote Creek year-round.

Seismic Retrofit construction activities downstream of the dam would have the same impacts on Sacramento hitch as described for rearing steelhead. The specific project component aquatic species rescue and relocation plan for dewatering activities outlined in the Project Description would reduce impacts of fish stranding during dewatering activities by having each contractor develop an aquatic species rescue and relocation plan that would need prior approval by NMFS and CDFW prior to implementation during localized dewatering for relevant construction components (LLOW construction and~~,~~ Cochrane Rd realignment~~, North Channel Extension~~). BMP BI-2 will further restrict any routine in-channel vehicle traffic during construction activities to the dry season work window. BMPs and AMMs implemented to reduce impacts on steelhead will also reduce impacts from in-channel construction activities downstream of the dam on Sacramento hitch. Noise and vibration disturbance or injury risk would be the same for near channel work that is not in channel as described for steelhead.

Staging and stockpiling immediately downstream of the dam would have the same impacts on Sacramento hitch as described for steelhead. BMPs and AMMs implemented to reduce impacts on steelhead will also reduce impacts from staging and stockpiling downstream of the dam on Sacramento hitch. In Year 5, blasting at the BHBA would have the same impacts on Sacramento hitch immediately downstream of the dam as described for steelhead. Construction and use of the temporary access road would also have the same impacts on Sacramento hitch as described for steelhead. BMPs and AMMs implemented to reduce impacts from the temporary access road on steelhead would also reduce impacts on Sacramento hitch.

Sacramento hitch are abundant and widely distributed in Coyote Creek (Leidy 2007, Valley Water 2021a); therefore, overall impacts on the Sacramento hitch population from Seismic Retrofit construction would not be substantial.

Additionally, the seismically retrofitted dam would be allowed to refill once ~~seismic~~ restrictions are lifted allowing more available habitat in the reservoir and storage for cold water pool management post-construction compared to the existing conditions baseline and the new, multi-level intake structure would allow more precise temperature control on downstream releases relative to the existing conditions baseline in the long-term. Hitch have broader temperature tolerance than steelhead so it may not benefit them directly, but lower temperatures would decrease suitability for non-native species within the creek system which would be a benefit. With regard to adverse impacts of refilling the reservoir, there would be no impact.

Overall, Seismic Retrofit construction activities will adversely impact hitch, but the impacts will not be substantial with the application of BMPs, and AMMs; therefore, Seismic Retrofit construction activities impacts would be less than significant on Sacramento hitch.

Seismic Retrofit (Anderson Dam) and Instream Flows Operation during Seismic Retrofit Construction

This section analyzes the impacts of Seismic Retrofit (Anderson Dam) and instream flows operations downstream of Anderson Dam during Seismic Retrofit Construction on Sacramento hitch compared with the Pre-FERC Order Baseline.

During Seismic Retrofit construction, generally, there would be wet seasons, spring reservoir drawdown, and dry construction seasons. During the wet season, the outlet of the dam would be fully open and all inflows to the reservoir would be diverted and released downstream as quickly as possible given the type of diversion (Stage 1 or Stage 2). During the wet seasons and the spring drawdown, the Stage 2 diversion would be constructed allowing faster drawdown, up to 6,000 cfs, of reservoir storage when needed, a considerably higher conveyance capacity than the Stage 1 diversion even paired with the existing outlet. In April, or when conditions allow following April, the reservoir would be drawn down to the elevation needed to conduct construction activities during the dry construction season. The rate of drawdown would depend on antecedent conditions in the watershed and the type of diversion in place (Stage 1 or Stage 2) but should take about 2-4 weeks. Once the reservoir has been drawn down to the correct elevation to initiate in-channel work, then the construction activity for that year would commence and any inflows coming into the reservoir would be diverted (or sometimes pumped) around the work area and released downstream. Sacramento hitch, which are found in the reservoir as well as below the dam, could be entrained in the outlet or diversion systems during reservoir dewatering, which could result in injury or mortality; however, fyke trapping in 2020 and 2021 indicated that at least some Sacramento hitch may successfully pass through the outlet during reservoir dewatering with minimal or no injury or mortality. Rapid dewatering could strand individuals along the banks of the reservoir or trap them in pools as water levels decrease. Sacramento hitch could also become trapped between the dam and the cofferdam and become stranded if they do not make it through the dam and downstream. It is not feasible to conduct a fish rescue and relocation effort between the dam and the cofferdam because the muddy conditions make it hazardous and unsafe for staff. However, Sampling conducted in Anderson Reservoir using boat electrofishing in 2017 and 2019, which was distributed throughout all quadrants of the reservoir did not detect Sacramento hitch in the system (Valley Water 2020~~-~~). Additionally, exploratory electrofishing in the reservoir in 2023, during FOCP, did not detect any hitch but it was limited in area surveyed. Based on this sampling, the abundance of Sacramento hitch if present at all seems low. If they are present in the reservoir, they can be reseeded each wet season, and the abundance in the reservoir would be a very small percentage of the overall population in the Coyote Creek watershed. Additionally, despite implementation of the FOCP Reservoir Drawdown and Operations Plan, water temperatures in Anderson Reservoir have not yet exceeded suitable conditions for rearing Sacramento hitch (less than 86 °F [30 °C]) (Moyle 2002) and dry season temperatures during Project would be similar to existing conditions or colder once the chillers are installed.

The drawdown activities would not result in adverse impacts to Sacramento hitch in Coyote Creek. This species is adapted to variable flow conditions, are non-migratory and have a broad window that spawning can occur.

Therefore, overall, the impacts from Seismic Retrofit (Anderson Dam) and Instream Flows Operation would be less than significant for Sacramento hitch population and their habitat.

Hydrology

During construction, hydrology downstream of the dam would be more dynamic during the wet season and follow a more natural flow regime that is driven by precipitation (see Section 3.11, *Hydrology* ~~*Hyrdology*~~). Hitch are well adapted to changing flow conditions in coastal watersheds and changes in hydrology would have no impact on hitch. Higher flows during Project construction may provide geomorphic processes~~)~~. Operation of Coyote Reservoir, bypassing flows through Anderson Reservoir to Coyote Creek, augmentation of streamflow in the FCWMZ using native water released through the dam, supplemented by imported water released through CDL, and additional downstream instream flow augmentation via the Cross Valley

Pipeline Extension following its construction, Valley Water would maintain suitable habitat for Sacramento hitch. Also, installation of the Cross Valley Pipeline Extension would help to maintain habitat used by Sacramento hitch in the reaches downstream of Ogier Pond. Therefore, overall, the impacts from changes in hydrology would be less than significant for Sacramento hitch population and their habitat.

Water Quality – Dissolved Oxygen and Temperature

Water quality is potentially limiting in the dry construction season when there is more risk of temperature increases and associated potential declines in dissolved oxygen. During the dry season work window, inflows passed through the reservoir combined with chilled water from the CDL would be at least 10 cfs. Chillers would be used to chill up to 10 cfs of imported water to within a more suitable temperature range for steelhead which is within the wide range of temperatures suitable for hitch and associated DO would also be in the suitable range for hitch so there would be no impacts from changes in DO and temperature on Sacramento hitch. Also imported water releases from the Cross Valley Pipeline Extension would continue to be used for groundwater recharge and to provide incidental instream flows to prevent dryback downstream of Ogier Ponds.

Water Quality - Sediment Transport During Wet Seasons and Spring Drawdown

During the wet season and spring drawdown, water would be drawn down quickly under the Stage 2 diversion. Drawing water down faster and keeping a lower elevation in the reservoir would result in increased sediment erosion and transport downstream during drawdowns and high-flow events following precipitation. This section evaluates the impacts of increased erosion and sediment transport in Coyote Creek to Alviso slough when bypassing flows from the reservoir to the creek during the wet season and during spring drawdowns. Effects of wet season bypass and reservoir drawdown on hitch within the reservoir are considered in the section above.

Sacramento hitch are assumed to be present within Coyote Creek from the estuary to Anderson Dam, spawning in the clean gravel of riffles after increased flows resulting from spring rains (Moyle 2002). Sacramento hitch are adapted to the high disturbance regimes typical of lower reaches of central coast watersheds, including warm water, and periodic increases in flow and suspended sediment (Moyle et al. 1982 ~~and Daniels 1982~~, Moyle 2002). Under all of the modeled sediment transport scenarios in all construction years, suspended sediment was not predicted to be high enough or to persist long enough in duration to pose a substantial risk to Sacramento hitch (Appendix F ~~G~~).

Following Year 6, the reservoir would be allowed to refill via inflows and, if possible, imported water up to the new maximum level and the FAHCE rule curves would be initiated. With the reservoir refilled, suspended sediment would decrease during constant inflow or precipitation events because the full reservoir would re-inundate previously exposed erodible and suspended sediment would return to near Pre-FERC Order Baseline Conditions.

Non-Native Species

Under existing conditions and construction, the assemblage or distribution of non-native fish species in Coyote Creek is not expected to change. Changes associated with the project will not provide habitat that is more suitable. The Anderson Reservoir drawdown activities could create conditions that may allow for increase access of non-native species to Coyote Creek. Actions taken by Valley Water during sampling activities and construction related dewatering will help reduce the abundance of non-native species. For the same reasons outlined here and further analyzed in the steelhead section, impacts on Sacramento hitch from the release of non-native species from Anderson Reservoir downstream would not be significant.

Instream Flows During Construction Summary

Overall, instream flows would maintain Sacramento hitch throughout the entire construction phase of the Project by providing flows, sediment concentrations, temperatures, and DO within a range that can support Sacramento hitch in Coyote Creek downstream of the dam. Also, compared to Pre-FERC Order Conditions flows bypassed through the reservoir would result in variable flows downstream, which is presumably beneficial for the native hitch that evolved in dynamic aquatic habitats.

Therefore, overall, the impacts from instream flows during construction would be less than significant for Sacramento hitch population and their habitat.

Conservation Measures Construction

The following Conservation Measures, Normal Operation of Coyote Reservoir and Construction Period Imported Water Releases and Operation of Chillers, do not have a construction component and were previously considered as part of the *Instream Flows during Seismic Retrofit Construction* under the *Seismic Retrofit Construction Activities Impacts Analysis,* so they are not discussed further in this section.

Impacts resulting from construction activities for the Conservation Measures that require construction are considered in this section. Conservation measure construction could impact Sacramento hitch in the short-term but would benefit Sacramento hitch in the long-term. Conservation Measure construction components that could impact Sacramento hitch are assessed in further detail in this section.

Ogier Ponds Conservation Measure Project

Similar to what was described above for steelhead, the Ogier Ponds CM would benefit Sacramento hitch through improved water quality (i.e., lower water temperature), enhanced fish passage, and reduced habitat for warm water, non-native fish, particularly that of predatory species, in the system compared to Pre-FERC Order and existing conditions. Construction of the Ogier Ponds CM could have short-term impacts on Sacramento hitch during localized dewatering and in-channel and near-channel construction activities that could degrade water quality downstream of the Ogier Ponds.

In-channel construction activities for the Ogier Ponds CM would have the similar impacts on Sacramento hitch as described for rearing steelhead, but the dry season work window and BMP BI-2 would not reduce impacts on Sacramento hitch because they can occur from the dam to Alviso Slough year-round, so impact reduction would mostly come from the aquatic species rescue and relocation plan that would be developed for Ogier Ponds CM. However, the in-dry season work window would minimize some impacts during part of the spawning season. Also, Sacramento hitch are more ubiquitous throughout Coyote Creek than steelhead, so localized effects would not impair the population of hitch within the Creek.

Noise and vibration disturbance or injury would be the same for near channel work that is not in-channel as described for steelhead. Cofferdam installation and diverting water around the work area would restrict rearing habitat and limit access to the FCWMZ upstream of Ogier Ponds. BMPs and AMMs implemented to reduce impacts on steelhead would also reduce impacts on Sacramento hitch from cofferdam installation and diverting water around the Ogier Ponds work area.

Excavation of ponds and new creek channel, filling of ponds, and staging and stockpiling for the Ogier Ponds CM would have the same impacts on Sacramento hitch as described for steelhead. BMPs and AMMs implemented to reduce impacts on steelhead would also reduce impacts from staging and stockpiling downstream of the dam on Sacramento hitch. Clearing and grubbing would remove vegetation and roots from the flood plain in preparation for excavation of the channel leading to some loss of habitat complexity for Sacramento hitch; however, adequately sized trees would be kept in place whenever feasible and, once the channel is reestablished in that area, the riparian corridor would be revegetated with native plants, benefiting fish habitat in the newly established channel.

The restored channel created via the Ogier Ponds CM will operate and function as a natural creek channel. There will be no management of flows or manipulation of features as a result of operations. Weirs will be activated infrequently when flow levels reach 2000 cfs and will be spillover, not requiring any actions.

Overall, Sacramento hitch are abundant in the watershed and occur upstream and downstream of Anderson Dam. They would be rescued and relocated during localized dewatering and the other identified BMPs and AMMs will minimize construction impacts. They are tolerant of warm temperatures and non-migratory, so temporary dewatered portions of the channel would not interfere with movement of the species. This species also tolerant of capture and handling that may occur during the relocation effort. For these reasons, Ogier Ponds CM construction would have less-than-significant impacts on Sacramento hitch in the short-term. Over the long-term, Sacramento hitch would benefit from improved water quality and decreased habitat for warm water, non-native predatory fish in the system.

Maintenance of the North Channel Reach ~~*North Channel Extension and Habitat Enhancement*~~

If there is water in the North Channel and Sacramento hitch are present, localized dewatering during ~~construction~~ maintenance activities could strand or trap them in pools, subjecting them to increased predation pressure or water quality degradation. Similar to what was described above for steelhead, Sacramento hitch would be rescued, relocated, and/or excluded from the ~~excluded with nets and a cofferdam would be built at the lower limit of the backwater to keep water from entering the~~ work area. ~~An aquatic species rescue and relocation plan for the North Channel Extension and Habitat Enhancement would reduce impacts of fish stranding during dewatering by implementing a fish rescue and relocation effort where any remaining Sacramento hitch in the upstream pool would be captured and relocated prior to and during dewatering the pool.~~ Pollution from construction equipment or sediment-laden materials could enter the channel if the channel were activated during high flows, but unlikely since all work will be conducted during the dry season. BMPs and AMMs implemented to reduce impacts on steelhead would also reduce impacts on Sacramento hitch.

~~Grading the North Channel to create positive drainage toward the existing south channel confluence and backwater and elimination of deep pools in the existing wetted channel is not anticipated to impact Sacramento hitch because they would have already been excluded from the work area and the area would be dewatered. Similar to steelhead, over the long-term, Sacramento hitch would benefit from reduced stranding and predation in the existing North Channel pools when they dewater following activation. Maintenance of Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach will maintain hitch spawning habitat that was improved under FOCP.~~

~~The continued placement of spawning gravels within Live Oak Restoration Reach proposed by this Project will incidentally provide new and enhanced spawning and rearing habitat for Sacramento hitch during the construction phase and after completion.~~ There may be temporary adverse effects during implementation, but through AMMs and BMPs those effects are reduced. The maintenance of the ~~Live Oak Restoration Reach~~ North Channel would have a long-term benefit for Sacramento hitch by maintaining spawning and other habitats that was enhanced during FOCP by directing high flows through the North Channel.

~~Placement of gravels has the potential to degrade water quality downstream of the work area if gravels and associated fine sediment enter the stream at the time of placement, which could impact hitch. However, gravels would not be placed directly in the channel, but would be placed adjacent to the channel or on benches above the channel so there would be no impact from introducing gravels to the channel at the time of placement. Also, when flows are high enough to mobilize the gravels in the gravel augmentation piles, there would already be elevated background levels of suspended sediment; therefore, additional sediment from the gravel piles would not add substantially to the total sediment that is already suspended during high flows.~~

~~Though it is not anticipated that gravels and associated fine sediment would enter the stream at the time of placement, measures would be implemented to protect Sacramento hitch in the unlikely event that this occurs. BMPs and AMMs implemented to reduce impacts on steelhead would also reduce impacts on Sacramento hitch by minimizing pollution to enter the channel from equipment or staging and stockpiling areas.~~

In the short term, construction impacts on Sacramento hitch would be less than significant. Over the long term, Sacramento hitch would benefit from Maintenance of the North Channel ~~Extension~~ Reach and helping maintain ~~maintaining~~ Live Oak Restoration Reach habitat that was enhanced during FOCP.

Maintenance of Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach

For the same reasons described for rearing steelhead, in the short-term, impacts on Sacramento hitch from placement and maintenance of spawning gravels during the dry season work window would be less than significant and, over the long-term, Sacramento hitch would benefit from Project maintenance of spawning habitat that was enhanced during FOCP.

Though it is not anticipated that fine sediment would enter the stream at the time of placement, measures would be implemented to protect Sacramento hitch in the unlikely event that this occurs. BMPs and AMMs implemented to reduce impacts on steelhead would also reduce impacts on Sacramento hitch by minimizing pollution to enter the channel from equipment or staging and stockpiling areas.

In the short-term, impacts on Sacramento hitch would not be substantial. Over the long-term, Sacramento hitch would benefit from maintaining spawning habitat that was enhanced during FOCP.

Sediment Augmentation Program

The Sediment Augmentation Program would improve geomorphic processes that create and maintain spawning habitat and reduce and reverse channel incision, benefiting Sacramento hitch in Coyote Creek. Sediment would be placed on the benches next to the channel in the CWMZ so that it would be mobilized during high-flow events. Placement of sediment has the potential to degrade water quality downstream of the work area if sediment enters the stream at the time of placement which could impact Sacramento hitch. However, sediment would be placed during the dry weather work window and would not be placed directly in the channel expect for the toe of the sediment pile and the rest ~~but~~ would be placed adjacent to the channel or on benches above the channel so there would be minimal ~~no~~ impact from introducing sediment to the channel at the time of placement. A small rise in suspended sediment could occur when sediment is mobilized during high-flow events which may cause acute physiological stress and impeded foraging ability in Sacramento hitch. However, the increased turbidity and any associated stress and impeded foraging would resolve quickly (less than 8 hours) and would not be sufficient in terms of sediment concentrations or duration to adversely impact Sacramento hitch. Furthermore, when flows are high enough to mobilize the sediment in the sediment augmentation piles there would already be elevated background levels of suspended sediment; therefore, additional sediment from the piles would not add substantially to the total sediment that is already suspended during high flows.

Disturbance or injury impacts and measures to protect Sacramento hitch would be the same as described for steelhead. In the short term, Sediment Augmentation Program impacts on Sacramento hitch would be less than significant. Over the long-term, Sacramento hitch would benefit from improved geomorphic processes that create and maintain spawning habitat and reduce and reverse channel incision.

Phase 2 Coyote Percolation Dam CM

Construction for the Phase 2 Coyote Percolation Dam CM requires localized dewatering during construction activities which has the potential to strand Sacramento hitch or trap them in pools, subjecting them to increased predation pressure or water quality degradation. Construction activities also have the potential to degrade water quality downstream of the work area due to increased suspended sediment or other materials in the water.

Similar to what was described above for steelhead, Sacramento hitch would be excluded from the work area with block nets and/or captured and relocated prior to and during dewatering. A dewatering and aquatic species rescue and relocation plan for the Phase 2 Coyote Percolation Dam CM would reduce impacts of fish stranding during localized dewatering by implementing a fish rescue and relocation effort. Expected acute physiological stress during rescue and relocation would be a lesser impact than likely mortality due to stranding, predation, and/or deteriorating water quality conditions if rescue and relocation during localized dewatering were not implemented. BMPs and AMMs implemented to reduce impacts from dewatering on steelhead will also reduce impacts on Sacramento hitch.

Sediment entering the channel from the construction work area would have the same impacts as described for steelhead, except the hitch are generally more tolerant of sediment than steelhead. BMPs and AMMs implemented to reduce impacts on steelhead, such as installing erosion control measures and minimizing pollution from construction equipment, would also reduce impacts from sediment on Sacramento hitch.

Overall, Phase 2 Coyote Percolation Dam CM construction would have less-than-significant impacts on Sacramento hitch.

Construction Monitoring

Construction Phase Fisheries Monitoring

Fisheries monitoring would provide valuable information to inform management of steelhead and other species in the study area and guide Valley Water and regulatory agencies in decision-making regarding the steelhead Fish Rescue and Relocation Plan. Water ~~temperature~~ quality monitoring, suspended sediment monitoring, sediment deposition monitoring, VAKI Riverwatcher adult escapement monitoring, spawning surveys, eDNA, ~~and~~ migration flow monitoring, PIT tag migration study, growth comparative study, non-native control methods, reptile monitoring, and terrestrial animal monitoring ~~are all non-invasive monitoring methods targeting steelhead data collection that~~ would have no impacts on Sacramento hitch. Sensitive habitat monitoring and groundwater monitoring would not adversely impact Sacramento hitch as these studies do not require in-channel sampling. Groundwater monitoring would not adversely impact Sacramento hitch because monitoring wells are located outside the active channel of Coyote Creek.

Sacramento hitch may be unintentionally captured during juvenile rearing studies ~~fishing surveys~~. Capturing and handling Sacramento hitch could cause acute physiological stress. Injury and mortality are rare but happen occasionally. Valley Water would be subject to the terms and conditions of their California Scientific Collecting Permits which include impact avoidance and minimization measures during these studies.

Construction Phase Fish Rescue and Relocation; Juvenile Rearing, Migration, and Growth

If monitoring of water temperature and DO indicates that conditions for rearing steelhead would become unsuitable within the Coyote Creek FCWMZ as a result of Seismic Retrofit construction activities, steelhead and Pacific lamprey would be rescued and relocated per the Fish Rescue and Relocation Plan. Capture methods would include backpack electrofishing and/or seining. Sacramento hitch may be incidentally captured during the steelhead and Pacific lamprey rescue efforts but would not be relocated as the species is more tolerant of high temperatures than steelhead (Moyle 2002, Leidy 2007). Also, Sacramento hitch may be captured during the juvenile rearing sampling which uses the same backpack electrofishing methods Sacramento hitch may be stunned/netted, captured, and handled causing acute physiological stress that would be temporary. Injury or mortality can happen occasionally but are rare. Most Sacramento hitch tolerate capture and handling and would be released quickly after capture to minimize this impact.

Invasive Species Monitoring and Control Plan

Impacts on and benefits to Sacramento hitch from implementing the Invasive Species Monitoring and Control Plan would be the same as outlined for steelhead. This plan would result in a reduction to potential predators to Pacific lamprey and would benefit the species in the short term.

Construction Monitoring Summary

Overall, construction monitoring would result in short-term, less-than-significant impacts on Sacramento hitch. In the long-term, data collection on the species and its habitat will allow Valley Water to better understand the species and guide any management that may be necessary.

Post-Construction Instream Flows Operations (FAHCE Rule Curves)

This section analyzes the impacts and benefits of implementing the FAHCE rule curves (i.e., the Project) compared with Pre-FERC Order Baseline Conditions and Future Baseline conditions downstream of the dam. Spawning and Incubation Habitat (February through July)

The Project is predicted to result in an increase in spawning and incubation habitat for Sacramento hitch. The steelhead section provides discussion of the extensive spawning habitat that was created under FOCP and would be maintained under the Project. Sacramento hitch have a wider range of physiological tolerance for temperatures and often spawn in warmer waters than steelhead. However, the steelhead spawning habitat restoration efforts would include gravels through both Maintenance of Live Oak Restoration Reach Conservation Measures and the Sediment Augmentation Program Conservation Measures. These programs maintain gravels sizes on a long-term basis that are also used by Sacramento hitch for spawning. Given a preference to spawn in slightly warmer waters, Sacramento hitch may shift their spawning habitat downstream once the FAHCE rule curves are implemented but spawning habitat should remain plentiful for Sacramento hitch, and the post-construction operations would result in similar amounts of spawning habitat while the restoration projects would increase spawning habitat.

The spawning and incubation habitat available for Sacramento hitch that might be present in the reservoir will not differ greatly compared to Pre-FERC Order Conditions. The reservoir operations will not reduce access to the habitat in the upstream creek systems.

Overall, the amount of spawning and incubation habitat under the Project would increase in Coyote Creek but may shift slightly downstream as compared to the Pre-FERC Order and future conditions baselines to remain in warmer waters once the FAHCE rule curves are implemented. If Sacramento hitch are present in Anderson Reservoir post construction operations will not influence access to spawning habitat.

Rearing

The Project is predicted to result in an increase in rearing habitat for Sacramento hitch compared to Pre-FERC Order and future conditions baseline. The steelhead section provides discussion of the extensive rearing habitat that was created under FOCP and would be maintained under the Project. Sacramento hitch have a wider range of physiological tolerance for temperatures and can tolerate warmer waters than steelhead. Therefore, all of the rearing habitat created for steelhead would also be usable by Sacramento hitch for rearing. The Sacramento hitch population is abundant, and habitat is plentiful in the watershed. Also, Sacramento hitch occur in the Coyote reservoir and tributaries and can continue to provide new Sacramento hitch downstream during high-flow events.

Overall, the amount of rearing habitat under the Project would increase.

Post-Construction Instream Flows (FAHCE Rule Curves) Summary

The post-construction instream flows would have no adverse impact on the Sacramento hitch population or its habitat, and would increase the amount of spawning, incubation and rearing habitat compared to Pre-FERC Order and future conditions.

Post-Construction Seismic Retrofit and Conservation Measures Operations, Maintenance, and Adaptive Management

All post-construction monitoring and maintenance activities that were previously described in the steelhead and Chinook salmon equivalent sections that were covered by the DMP, SMP, and PMP also apply to the Sacramento hitch analysis and are not repeated here. Anderson Dam and Conservation Measures post-construction maintenance would have less-than-significant impacts on Sacramento hitch in the short term and operations, maintenance, and monitoring would have long-term benefits to southern coastal roach and their habitat.

Anderson Dam Post-Construction Operations, Maintenance, and Monitoring

Sacramento hitch would have the same short-term less than significant impacts from Anderson Dam maintenance and monitoring as steelhead. Sacramento hitch may benefit from more flexible operations of Anderson Dam as were described for steelhead. However, Sacramento hitch have high-temperature tolerance, therefore benefits or impacts from dam operations would be negligible for the Sacramento hitch population in the watershed.

Ogier Ponds CM Operations, Maintenance, and Monitoring

The restored channel created via the Ogier Ponds CM will operate and function as a natural creek channel. There will be no management of flows or manipulation of features as a result of operations. Weirs will be activated infrequently when flow levels reach 2000 cfs and will be spillover, not requiring any actions.

Sacramento hitch would have the same short-term less-than-significant impacts from operations, maintenance and monitoring and the same benefits from a restored channel as were described for steelhead. These improvements are expected to support a larger and more resilient Sacramento hitch population in the watershed.

North Channel Reach ~~Extension~~ Operations, Maintenance, and Monitoring

Sacramento hitch would have the same short-term, less-than-significant impacts and the same benefits from enhanced conveyance of geomorphic flows and decreased stranding risk as were described for steelhead. These improvements would support a larger and more resilient Sacramento hitch population in the watershed.

Spawning Gravel and Rearing Habitat Enhancements in the Live Oak Restoration Reach ~~and Sediment Augmentation Program~~ Operations, Maintenance, and Monitoring

Sacramento hitch would have the same short-term, less-than-significant impacts as described for steelhead. Even though the goals and objectives of the spawning gravel ~~and sediment augmentation program~~ are aimed at steelhead, there would be overlap with the gravel sizes Sacramento hitch need for egg incubation and other habitat needs (Moyle 2002) providing a benefit. These improvements would support a larger and more resilient Sacramento hitch population.

Sediment Augmentation Program Maintenance, and Monitoring

Sacramento hitch would have the same short-term, less-than-significant impacts as described for steelhead. Even though the goals and objectives of the Sediment Augmentation Program are aimed at steelhead, the general improvement in geomorphic processes in Coyote Creek would benefit Sacramento hitch as well (Moyle 2002). These improvements would support a larger and more resilient Sacramento hitch population.

Phase 2 Coyote Percolation Dam CM Operations, Maintenance, and Monitoring

Sacramento hitch would have the same short-term, less-than-significant impacts from maintenance of Phase 2 Coyote Percolation Dam as described for steelhead. Sacramento hitch are non-migratory so there would be no impact from post-construction operations of the Coyote Percolation Dam long-term.

Project and FAHCE Adaptive Management

As discussed for steelhead, Chinook salmon, and Pacific lamprey, refinements under the AMP would likely have impacts similar to those discussed in this EIR under Conservation Measures Construction but at a much smaller scale for Ogier Ponds and the Coyote Percolation Dam. Therefore, some short-term impacts would be predicted if there are any construction components to the adaptive management measures and long-term benefits would be predicted given that the AMP is aimed at enhancing steelhead and Chinook salmon habitat, and Sacramento hitch have less stringent habitat needs.

Under the AMP, there would be compliance monitoring, validation monitoring, effectiveness monitoring, and a long-term trend monitoring program. Compliance and validation monitoring would collect data through passive monitoring technology and habitat surveys and would have no impact on Sacramento hitch. Long-term trend monitoring would include passive monitoring such as VAKI Riverwatchers or PIT tag readers using noninvasive technology and would have no impact on Sacramento hitch.

Long-term monitoring would also include stunning through electrofishing, capturing/netting, crowding, handling, DNA sampling, and PIT tagging steelhead. These activities can cause acute physiological stress and occasional (but rare) incidental injury and/or mortality if Sacramento hitch are stunned, captured and handled during electrofishing surveys for steelhead. Backpack electrofishing surveys are limited to relatively shallow habitats and will not cover deeper habitats where Sacramento hitch may be abundant. Electrofishing would follow standard NMFS and CDFW survey protocols, which would minimize injury and mortality of Sacramento hitch during stunning, handling, and sampling.

The monitoring program would provide valuable long-term individual and population information for steelhead, Chinook salmon, and Sacramento hitch, that could be used to adjust components of the Project through the AMP to be more beneficial to native fish over the long term. Any adaptive management measures that are implemented would likely benefit Sacramento hitch as well. Information about Sacramento hitch would also be collected while monitoring steelhead and Chinook salmon. Any new information would help inform future conservation management efforts aimed at Sacramento hitch by providing best available information. Therefore, the impacts of monitoring activities implemented under the AMP would not be substantial and may prove to be beneficial for Sacramento hitch.

The post-construction operations flow releases from Anderson Dam may also be modified to achieve better geomorphic function of the river system via floodplain inundation, spawning gravel maintenance, and channel formation which would address historical blockage of sediment by Anderson Dam and Reservoir restoring more natural geomorphic processes downstream of the dam benefiting Sacramento hitch and their habitat.

Therefore, there would be less-than-significant, short-term impacts on Sacramento hitch from Project and FAHCE adaptive management and likely long-term benefits.

Significance Conclusion Summary for Sacramento Hitch

The Project would result in less than significant impacts on Sacramento hitch from Seismic Retrofit Project Construction; Conservation Measures Construction; Construction Monitoring; Post-Construction Instream Flows Operations; and Anderson Dam and Conservation Measures Maintenance and Adaptive Management. The Project would benefit Sacramento hitch and their habitat through Conservation Measures Construction; and Anderson Dam and Conservation Measures Operations, Maintenance, and Adaptive Management. Overall, impacts on Sacramento hitch would be short-term and **less than significant**. There would be long-term benefits to the Sacramento hitch population and habitat.

Mitigation Measures

No mitigation is required.

Impact FR-1e: Southern Coastal Roach (Less than Significant)

Seismic Retrofit Construction

Seismic Retrofit Construction Activities

Construction activities in the construction footprint could impact southern coastal roach individuals or their habitat from immediately downstream of Anderson Dam to Alviso Slough. Construction activities upstream of the dam in the reservoir would not impact southern coastal roach individuals directly as this species has not been observed in the reservoir (Valley Water 2020c ~~2019c~~). There would be increased sediment transport compared with the existing conditions baseline when the reservoir is held at low elevations because sediment that is usually inundated in the reservoir would be exposed and become more erodible during precipitation events. While associated with construction, sediment transport downstream of the dam is more applicable to the construction phase flow operations that would carry the sediment downstream; therefore, impacts from increased sediment transport on coastal roach downstream of the dam are analyzed in the next section *Seismic Retrofit (Anderson Dam) and Instream Flows Operations during Seismic Retrofit Construction* while this section analyzes the impacts of seismic retrofit construction activities (e.g., excavation, fill, use of heavy equipment, pile driving, staging, and stockpiling, etc.).

Southern coastal roach are present in Coyote Creek in various life stages throughout the year. Southern coastal roach would be present in Coyote Creek year-round but spawning specifically takes place between March and July. Southern coastal roach occupy similar habitats as Sacramento hitch in Coyote Creek downstream of the dam; impacts on southern coastal roach from construction activities downstream of the dam would be the same as those described for Sacramento hitch.

Southern coastal roach could be impacted by in-channel construction activities, in-channel and near channel noise and vibration, excavation, fill, heavy equipment operation and potential for decreased water quality from pollution from those activities as well as staging and stockpiling area and associated equipment. Pollutants discharged may include increased sediment in Coyote Creek, fuels, lubricants and other construction related pollutants. The specific Project component aquatic species fish rescue and relocation plans for dewatering activities outlined in the Project Description would reduce impacts of fish stranding during localized dewatering activities as discussed for hitch. BMP BI-2 will minimize some impacts of construction activities on spawning but would not address other life stages.

Overall, Seismic Retrofit construction activities will adversely impact southern coastal roach downstream of the dam, but the impacts will not be substantial with the application of relevant BMPs and AMMs, and after application of the dewatering and aquatic species rescue and recovery plans for localized dewatering; therefore, Seismic Retrofit construction activities impacts would be less than significant on southern coastal roach.

Seismic Retrofit (Anderson Dam) and Instream Flows Operations during Seismic Retrofit Construction

Impacts and benefits from Anderson Dam and instream flows operations during Seismic Retrofit construction on southern coastal roach would be essentially the same as those described for Sacramento hitch downstream of the dam because the two species overlap considerably in habitat needs and both could occur downstream of the dam to Alviso Slough. Overall, the impacts from Anderson Dam and instream flows operations during construction would be less than significant for the southern coastal roach population and habitat.

Conservation Measures Construction

The following Conservation Measures, Normal Operation of Coyote Reservoir and Construction Period Imported Water Releases and the Operation of Chillers, do not have a construction component and were previously considered as part of the *Instream Flows during Seismic Retrofit Construction* under the *Seismic Retrofit Construction Activities Impacts Analysis,* so they are not discussed further in this section.

Construction activities for the Conservation Measures that require construction are considered in this section. Conservation Measures construction could impact southern coastal roach in the short-term but would benefit southern coastal roach in the long-term. Conservation measure construction components that could impact southern coastal roach are assessed in further detail in this section.

Ogier Ponds CM

Similar to what was described above for steelhead, the Ogier Ponds CM would benefit southern coastal roach through increased rearing habitat, improved water quality (i.e., lower water temperature), enhanced fish passage, and reduced habitat for warm water, non-native fish, particularly that of predatory species, in the system compared to Pre-FERC Order Conditions. Construction of the Ogier Ponds CM could have short-term impacts on southern coastal roach during localized dewatering and in-channel and near-channel construction activities that could degrade water quality downstream of the Ogier Ponds.

In-channel and near channel construction activities for the Ogier Ponds CM would have the same impacts on southern coastal roach as described for Sacramento hitch. The dry season work window would minimize some impacts on spawning, but individuals would be present year-round. The same BMPs, AMMs, dewatering, and aquatic species rescue and relocation plan for localized dewatering will also apply to southern coastal roach.

Southern coastal roach are common in reaches that support native fish and are less common in reaches with non-native, particularly predatory species (Moyle 2002). One of the results of the Ogier Ponds CM would be to reduce habitat for non-native, piscivorous species which would benefit southern coastal roach.

The restored channel created via the Ogier Ponds CM will operate and function as a natural creek channel. There will be no management of flows or manipulation of features as a result of operations. Weirs will be activated infrequently when flow levels reach 2000 cfs and will be spillover, not requiring any actions.

Overall, southern coastal roach are abundant in the watershed and occur downstream of Anderson Dam. They would be rescued and relocated during localized dewatering and the other identified BMPs and AMMs would minimize construction impacts. They are tolerant of warm temperatures and non-migratory so temporary dewatered portions of the channel would not interfere with important life history phases that require migration. For these reasons, Ogier Ponds CM construction would have less-than-significant impacts on southern coastal roach in the short-term. Over the long-term, southern coastal roach would benefit from improved water quality and decreased habitat for warm water, non-native predatory fish in the system.

Maintenance of the North Channel Reach ~~North Channel Extension~~

If there is water in the North Channel and southern coastal roach are present, localized dewatering during ~~construction~~ maintenance activities could strand or trap them in pools, subjecting them to increased predation pressure or water quality degradation. Similar to what was described above for steelhead, ~~southern coastal roach would be excluded with nets and a cofferdam would be built at the lower limit of the backwater to keep water from entering the work area. The~~ the Aquatic Species Rescue and Relocation Plan for Maintenance of the North Channel ~~Extension~~ Reach would reduce impacts of fish stranding during dewatering by implementing a fish rescue and relocation effort where any remaining southern coastal roach in any ~~the upstream~~ pools would be captured and relocated prior to and during dewatering the pool. Pollution from construction equipment or sediment-laden materials could enter the channel when it is activated during high flows. BMPs and AMMs implemented to reduce impacts on steelhead will also reduce impacts on southern coastal roach so that they are less than significant.

~~Grading the North Channel to create positive drainage toward the existing confluence with the South Channel backwater and elimination of deep pools in the existing wetted channel is not anticipated to impact southern coastal roach, because they would have already been excluded from the work area and the area would be dewatered.~~ Similar to Sacramento hitch, over the long term, southern coastal roach would benefit from the protection of enhanced habitat in the South Channel by high flow conveyance through the North Channel. ~~reduced stranding and predation in the existing North Channel pools when they dewater following activation.~~

Maintenance of Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach

For the same reasons described for Sacramento hitch, in the short-term, impacts on southern coastal roach from placement and maintenance of spawning gravels during the dry season work window would be less than significant and, over the long-term, southern coastal roach would benefit from Project maintenance of spawning habitat that was enhanced during FOCP.

Though it is not anticipated that ~~gravels and associated~~ fine sediment would enter the stream at the time of placement, measures would be implemented to protect southern coastal roach in the unlikely event that this occurs. BMPs and AMMs implemented to reduce impacts on steelhead would also reduce impacts on southern coastal roach by minimizing pollution to enter the channel from equipment or staging and stockpiling areas.

In the short-term, impacts on southern coastal roach would not be substantial. Over the long-term, southern coastal roach would benefit from maintaining spawning habitat that was enhanced during FOCP.

Sediment Augmentation Program

The Sediment Augmentation Program would improve geomorphic processes that create and maintain spawning habitat and reduce and reverse channel incision, benefiting southern coastal roach in Coyote Creek. Sediment would be placed on the benches next to the channel in the FCWMZ during the dry season work window, so that it would be mobilized during high-flow events. Placement of sediment has the potential to degrade water quality downstream of the work area if sediment enters the stream at the time of placement which could impact southern coastal roach. However, sediment would not be placed directly in the channel except for the toe of the sediment pile, the rest ~~but~~ would be placed adjacent to the channel or on benches above the channel so during dry weather there would be minimal ~~no~~ impact from introducing sediment to the channel at the time of placement. A small rise in suspended sediment could occur when sediment is mobilized during high-flow events which may cause acute physiological stress and impede foraging ability in southern coastal roach. However, the increased turbidity and any associated stress and impeded foraging ability would resolve quickly (less than 8 hours) and would not adversely impact southern coastal roach. Furthermore, when flows are high enough to mobilize the sediment in the sediment augmentation piles there would already be elevated background levels of suspended sediment; therefore, additional sediment from the piles would not add substantially to the total sediment that is already suspended during high flows.

Disturbance or injury impacts and measures to protect southern coastal roach would be the same as described for steelhead, but provide a conservative assessment as California roach are more tolerant of suspended sediment. In the short-term, impacts on southern coastal roach would be less than significant. Over the long-term, southern coastal roach would benefit from improved geomorphic processes that create and maintain spawning habitat and reduce and reverse channel incision.

Phase 2 Coyote Percolation Dam CM

The Phase 2 Coyote Percolation Dam Fish Passage Enhancement construction activities to complete the conservation measure could have short-term impacts on southern coastal roach. Construction of this Conservation Measure requires localized dewatering during construction activities which has the potential to strand southern coastal roach or trap them in pools, subjecting them to increased predation pressure or water quality degradation. Construction activities also have the potential to degrade water quality downstream of the work area due to increased suspended sediment or other materials in the water.

Similar to what was described above for Sacramento Hitch, southern coastal roach would be excluded from the work area with block nets and/or captured and relocated prior to and during dewatering. The Aquatic Species Rescue and Relocation Plan for the Phase 2 Coyote Percolation Dam CM would reduce impacts of fish stranding during dewatering by implementing a fish rescue and relocation effort. Expected acute physiological stress during rescue and relocation would be a lesser impact than likely mortality due to stranding, predation, and/or deteriorating water quality conditions if rescue and relocation during localized dewatering were not implemented. BMPs and AMMs implemented to reduce impacts from dewatering on steelhead will also reduce impacts on southern coastal roach.

Sediment entering the channel from the construction work area would have the same impacts as described for steelhead. BMPs and AMMs implemented to reduce impacts on steelhead, such as installing erosion control measures and minimizing pollution from construction equipment, will also reduce impacts from sediment on southern coastal roach.

Construction impacts on southern coastal roach would be short term and less than significant.

Construction Monitoring

Construction Phase Fisheries Monitoring

Fisheries monitoring would provide valuable information to inform management of steelhead and other species in the study area and guide Valley Water and regulatory agencies in decision making regarding the Fish Rescue and Relocation Plan. Water ~~temperature~~ quality monitoring, suspended sediment monitoring, sediment deposition monitoring, VAKI Riverwatcher adult escapement monitoring, spawning surveys, ~~sediment monitoring,~~ eDNA, ~~and~~ migration flow monitoring, PIT tag migration study, growth comparative study, non-native control methods, reptile monitoring, and terrestrial animal monitoring ~~are all non-invasive monitoring methods targeting steelhead data collection that~~ would have no impacts on southern coastal roach. Sensitive habitat monitoring and groundwater monitoring would not adversely impact southern coastal roach as these studies do not require in-channel sampling. Groundwater monitoring would not adversely impact southern coastal roach, because monitoring wells are located outside the active channel of Coyote Creek.

Southern coastal roach may be unintentionally captured during ~~bi-annual~~ juvenile rearing ~~monitoring~~ studies. Capturing and handling southern coastal roach could cause acute physiological stress. Injury and mortality are rare but happen occasionally. Valley Water would be subject to the terms and conditions of their California Scientific Collecting Permits, which include impact AMMs during these studies.

Construction Phase Fish Rescue and Relocation; Juvenile Rearing, Migration, and Growth

If monitoring of water temperature and DO indicates that conditions for rearing steelhead would become unsuitable within the Coyote Creek FCWMZ as a result of Seismic Retrofit construction activities, steelhead would be rescued and relocated per the Fish Rescue and Relocation Plan. Capture methods would include backpack electrofishing and/or seining. Southern coastal roach may be incidentally captured during the steelhead rescue efforts but would not be relocated as the species is more tolerant of high temperatures and low dissolved oxygen than steelhead (Moyle et al. 2015). Southern coastal roach may be stunned/netted, captured, and handled causing acute physiological stress. Injury or mortality can happen but are rare. Most southern coastal roach tolerate capture and handling and would be released quickly after capture to minimize this impact.

Invasive Species Monitoring and Control Plan

Impacts on and benefits to southern coastal roach from implementing the Invasive Species Monitoring and Control Plan would be the same as outlined for steelhead. This plan would result in a reduction to potential predators to California roach and would benefit the species in the short-term.

Construction Monitoring Summary

Overall, construction monitoring would result in less-than-significant impacts on southern coastal roach in the short-term.

Post-Construction Instream Flows Operations (FAHCE Rule Curves)

Impacts on and benefits to southern coastal roach from implementing the FAHCE rule curves would be essentially the same as Sacramento hitch downstream of Anderson Dam, as these species have very similar life history requirements. Overall, the amount of spawning and incubation habitat under the Project is anticipated to increase in Coyote Creek but may shift slightly downstream as compared to the Pre-FERC Order and future conditions baselines to remain in warmer waters once the FAHCE rule curves are implemented. If southern coastal roach are present in Anderson Reservoir post construction operations will not influence access to spawning habitat.

Post Construction Seismic Retrofit and Conservation Measures Operations, Maintenance, and Adaptive Management

All post-construction monitoring and maintenance activities that were previously described in the steelhead and Chinook salmon equivalent sections that were covered by the DMP, SMP, and PMP also apply to the southern coastal roach analysis and are not repeated here. Anderson Dam and Conservation Measures post-construction maintenance would have less-than-significant impacts on southern coastal roach in the short-term and operations, maintenance, and adaptive management would have long-term benefits to southern coastal roach and their habitat.

Significance Conclusion Summary for Southern Coastal Roach

The Project would result in impacts on southern coastal roach from Seismic Retrofit Project Construction; Conservation Measures Construction; Construction Monitoring; and Anderson Dam and Conservation Measures Operations, Maintenance, and Adaptive Management. The Project would benefit southern coastal roach and their habitat through Conservation Measures Construction; and Anderson Dam and Conservation Measures Operations, Maintenance, and Adaptive Management. Overall, impacts on southern coastal roach would be **less than significant** in the short term. There would be long-term benefits to the southern coastal roach population and habitat.

Mitigation Measures

No mitigation is required.

Impact FR-1f: Longfin Smelt (Less than Significant Impacts)

Seismic Retrofit Construction

Seismic Retrofit Construction Activities

The Seismic Retrofit construction footprint is located ~~over 25~~ approximately 32 stream miles upstream from the tidally influenced portions of Coyote Creek Watershed. Longfin smelt are present in nearshore waters where Coyote Creek meets San Francisco Bay. Larvae, juveniles and adults are typically found in salinity ranges greater than 2 ppt (Rosenfield 2010). Although exact locations of spawning adults are unknown, within the San Francisco Bay spawning appears to occur near the fresh-salt water mixing zone (Rosenfield 2010). It is thought the selection of a spawning site may be within an area that allows the transport of larvae into the fresh-salt water mixing zone as it is both a productive and turbid area within the San Francisco Bay (Rosenfield 2010). Given this information, it is unlikely for longfin smelt of any life-history stage to occur upstream of the tidally influenced portions of Coyote Creek Watershed. Therefore, Seismic Retrofit construction activities within the construction footprint are predicted to have no impacts directly on longfin smelt individuals or their habitat.

Seismic Retrofit and Instream Flows Operations during Seismic Retrofit Construction

Increased sediment transport associated with dewatering the reservoir and exposing erodible sediment that can be transported during precipitation events could impact longfin smelt individuals and their habitat within the tidally influenced portions of Coyote Creek.

There is evidence that longfin smelt spawn in the intertidal portion of Coyote Creek but there are many uncertainties surrounding spawning longfin smelt, including suspended sediment tolerances during the incubation period. However, due to the known primary spawning period (typically between February and April) and the fact that within central California winter rain events typically occur in this time period and lead to elevated levels of suspended sediment, it is assumed the species can tolerate some levels of suspended sediment during their incubation period.

Little scientific literature exists regarding the effects of suspended sediment on rearing and adult longfin smelt. However, the negative effects of suspended sediment on delta smelt (*Hypomesus transpacificus*) are minimal and longfin smelt are often associated with environments with higher turbidity (Gross et al. 2021). It is likely longfin smelt have similar suspended sediment tolerances as delta smelt, and possibly prefer habitat with seasonal sediment increases similar to delta smelt (Gross et al. 2021). In addition, turbidity due to suspended sediment is thought to shield longfin smelt larvae and juveniles from predators as they are weak swimmers (Rosenfield 2010). Potential suspended sediment increases at the mouth of Coyote Creek due to Seismic Retrofit construction would be temporary, would occur with seasonal precipitation events, and any adult longfin smelt individuals in the area would be able to behaviorally regulate their exposure by swimming to another area of the San Francisco Bay or tidally influenced creek systems so impacts would be less than significant.

Inorganic sediment inputs are critical to the health of the bay in the near term. These inputs are important in fighting climate change in the future and provide long-term marsh resilience to sea level rise (Dusterhoff et al. 2021). Tidally influenced areas in the San Francisco Bay are unlikely to naturally receive enough of a sediment input to survive sea level rise in the future (Dusterhoff et al. 2021). Increased sediment transported during precipitation events due to Seismic Retrofit construction activities may benefit the health of the Bay in the long term by resulting in more inorganic sediment than would otherwise be transported. Therefore, in the long-term, increased sediment transport downstream of the construction footprint may benefit the health of South San Francisco Bay as a whole, which would benefit native species in the area including longfin smelt.

Longfin smelt forage and spawn in tidally-influenced portions of Coyote Creek, where refugia with cooler temperatures are present. Smelt have adapted to thrive in intertidal delta conditions, where periodic high flows transporting substantial suspended sediment is common. In the Delta Conveyance EIR DWR has explored options for increasing suspended sediment and turbidity to improve conditions for smelt species (DWR 2022). It is expected that reservoir drawdowns and flows passing through the drained Anderson Reservoir would increase the amount of suspended sediment being transferred downstream (see the Steelhead Construction Phase Water Quality, Sediment Transport During Wet Season and Spring Drawndown section). For these reasons, the increase in flows and suspended sediment in the intertidal areas compared to Pre-FERC Order Conditions is likely to benefit longfin smelt, and any adverse impacts from sediment transport would be less than significant.

Conservation Measures Construction

The following Conservation Measures, Normal Operation of Coyote Reservoir Construction Period Imported Water Releases, Geomorphic Flow Plan and the Operation of Chillers, do not have a construction component and were previously considered as part of the *Instream Flows during Seismic Retrofit Construction* under the *Seismic Retrofit Construction Activities Impacts Analysis,* and would not impact longfin smelt.

Construction and maintenance activities for the Conservation Measures that require such activities are assessed further in this section.

Ogier Ponds CM

The Ogier Ponds CM construction footprint is located over 25 ~~20~~ miles upstream from the tidally influenced portions of Coyote Creek Watershed. Longfin smelt do not occur within or near the Ogier Ponds CM construction footprint. Therefore, Ogier Ponds CM construction activities within the construction footprint are predicted to have no direct impact on longfin smelt individuals or their habitat. Construction activities including staging and stockpiling, vegetation removal on the banks, filling in Pond 1 and 5, partially filling Pond 2, and 4, constructing an earthen berm, installing overflow weirs, and restoring the Coyote Creek Channel have the potential to temporarily degrade water quality downstream of the work area at the time of construction or thereafter due to increased suspended sediment or other materials in the water which could impact longfin smelt located downstream of the Ogier Ponds.

However, during the in-channel work window, longfin smelt adults are not present in the study area and only larval juveniles may be present in the tidal reaches well downstream of the work area for Ogier. Either way, flows are not expected to be high enough to carry elevated levels of suspended sediment 25 ~~20~~ miles downstream to where longfin smelt occur. Also, dewatering prior to construction would minimize sediment transport downstream. Following the in channel work window, the construction site would undergo winterization and the same BMPs and VHP conditions discussed in the steelhead impact assessment would minimize suspended sediment transported downstream during high flows. Even if there were elevated levels of suspended sediment, the species has high tolerance of suspended sediment and even a preference for associated turbidity so there would be no adverse impacts on longfin smelt from Ogier Ponds CM construction.

Maintenance of the North Channel Reach ~~North Channel Extension~~

The North Channel ~~Extension construction footprint~~ Reach is located over 30 ~~25~~ miles upstream from the tidally influenced portions of Coyote Creek Watershed. Longfin smelt are not present within or near the North Channel Reach ~~Extension construction footprint~~. Therefore, North Channel ~~Extension~~ maintenance ~~construction~~ activities ~~within the construction footprint are predicted to~~ would have no direct impact on longfin smelt individuals or their habitat. ~~Construction activities have the potential to temporarily degrade water quality downstream of the work area due to increased suspended sediment or other materials in the water.~~

Also ~~However~~, during the in-channel work window, longfin smelt adults would not be present in the study area and flows are not expected to be high enough to carry elevated levels of suspended sediment 30 ~~25~~ miles downstream to where larval longfin smelt could occur. Also, dewatering prior to ~~construction~~ maintenance, when needed, would minimize sediment transport downstream. However, even if there were elevated levels of suspended sediment, the species has high tolerance of suspended sediment and even a preference for associated turbidity and impacts so there would be no adverse impacts on longfin smelt from maintenance of the North Channel Reach ~~Extension construction~~.

Maintenance Activities at the Live Oak Restoration Reach

The Live Oak Restoration Reach footprint is located over 30 ~~25~~ miles upstream from the tidally influenced portions of Coyote Creek Watershed. Longfin smelt do not occur within or near the Live Oak Restoration Reach footprint. Therefore, Live Oak Restoration Reach maintenance activities within the construction footprint would have no direct impact on longfin smelt individuals or their habitat. Placement of gravels during the work window and maintaining habitat complexity has the potential to temporarily degrade water quality downstream of the work area if ~~gravels and associated~~ fine sediment enters the stream or construction equipment moving and placing habitat complexity features disturbs erodible material.

However, during the in-channel work window, adult longfin smelt would not be present in the study area and flows are not expected to be high enough to carry elevated levels of suspended sediment 30 ~~25~~ miles downstream to where larval longfin smelt could occur. Also, silt curtains and a belting conveyor would be used to place gravel minimizing impacts to aquatic habitat. The same BMPs and VHP conditions used to minimize erosion and sediment transport discussed in the steelhead impact assessment would minimize suspended sediment transported downstream. ~~Also, when flows are high enough to mobilize the gravels in the gravel augmentation piles, there would already be elevated background levels of suspended sediment; therefore, additional sediment from the gravel piles is unlikely to substantially add to the total sediment in a way that would impact longfin~~ Longfin smelt ~~that~~ have a high tolerance of suspended sediment and even a preference for associated turbidity so there would be no adverse impacts on longfin smelt from maintenance of spawning gravel and rearing habitat improvements in the Live Oak Restoration Reach.

Sediment Augmentation Program

The Sediment Augmentation Program resulting in placement of coarse sediments and spawning gravels within the CWMZ located 25 to 30 ~~17 to 25~~ miles upstream of the intertidal portion of Coyote Creek would have the same potential impacts as maintenance of the Live Oak Restoration Reach discussed in the section above, and the same justification for no adverse impacts to longfin smelt.

Phase 2 Coyote Percolation Dam CM

The Phase 2 Coyote Percolation Dam CM construction footprint is located ~~over 17~~ approximately 22 stream miles upstream from the tidally influenced portions of Coyote Creek Watershed. Longfin smelt do not occur within or near the Phase 2 Coyote Percolation Dam CM construction footprint. Therefore, Phase 2 Coyote Percolation Dam CM construction activities within the construction footprint are predicted to have no direct impact on longfin smelt individuals. Construction activities have the potential to temporarily degrade water quality downstream of the work area due to increased suspended sediment or other materials in the water.

However, during the dry season work window, longfin smelt adults are not likely to be present in the study area and flows are not expected to be high enough to carry elevated levels of suspended sediment 22 ~~17~~ miles downstream to where longfin smelt larvae may occur. Also, the construction site would be dewatered prior to construction further avoiding sediment transport impacts. Following the in-channel work window, the construction site would undergo winterization and the same BMPs and VHP conditions discussed in the steelhead impact assessment would minimize suspended sediment transported downstream during high flows. Even if there were elevated levels of suspended sediment, the species has high tolerance of suspended sediment and even a preference for associated turbidity so there would be no adverse impacts to longfin smelt from Phase 2 Coyote Percolation Dam CM.

Construction Monitoring

Longfin smelt would not be present during monitoring activities in the locations where monitoring activities that would affect the channel would occur; therefore, there would be no impact on longfin smelt from construction monitoring.

Post-Construction Instream Flows Operations (FAHCE Rule Curves)

Longfin smelt spawning occurs in the intertidal sloughs of the study area. These tidally influenced areas are ~~over 25~~ approximately 32 stream miles from Anderson Dam and longfin smelt likely occur too far downstream to be impacted by the Project flow operations. The species' habitat is greatly influenced by tidal action and freshwater inputs from tributaries; therefore, any change in flow operations is likely muted and negligible by the time water from the reservoir reaches the intertidal zone.

Additional analyses of potential changes in salinity using the largest monthly average value of changes in flow for Coyote Creek) were conducted; changes in salinity were selected as the best indicator of environmental changes to estuarine habitat that could be caused by post construction operations based upon the FAHCE rule curves. These analyses showed an extremely small change in salinity in the intertidal zone—a net increase in salinity of only about 0.043 percent from the FAHCE rule curves, when compared with the total volume of the South Bay Estuary of 86 million cubic meters. This analysis is provided in Appendix L of the Final EIR. Also, a 1998 USGS report (~~USGS~~ Bovee et al. 1998) on salinity in the South San Francisco Bay suggests that salinity changes in the South Bay estuary are driven by large storm events—less so by reservoir releases. The results of these salinity studies can be extrapolated to anticipated effects of post-construction FAHCE rule curve reservoir operations on other water quality constituents in the intertidal zone. The implementation of the FAHCE rule curves, which would increase reservoir releases by 10 to 20 cubic feet per second, a miniscule amount of fresh water compared with the total South Bay volume or the typical runoff from a winter storm event (less than 1 percent), would not result in a discernable change from the Pre-FERC Order Baseline Condition or future conditions baseline within the tidally influenced areas or estuary. Under FAHCE, the natural range and frequency of freshwater flows experienced by the river systems would not change and, by inference, the ecological habitats and other water quality parameters in these tidal prism areas should not be affected by post-construction operations.

Given the above analysis, the FAHCE rule curves are unlikely to cause any meaningful effects on the salinity or other water quality parameters or biological features relevant to longfin smelt habitat suitability in tidally influenced areas and the South Bay estuary. Given these results, there would be no impact of the post-construction operations (FAHCE rule curves) on longfin smelt.

Post-Construction Seismic Retrofit and Conservation Measures Operations, Maintenance, and Adaptive Management

All post-construction monitoring and maintenance activities that were previously described in the steelhead and Chinook salmon equivalent sections that will be covered by the DMP, SMP, and PMP and associated CEQA compliance also apply to the longfin smelt analysis and are not repeated here.

Anderson Dam Post-Construction Operations

Longfin smelt occur too far downstream to be impacted by or benefit from increased operational flexibility at Anderson Dam because longfin smelt habitat is also greatly influenced by tidal action and freshwater inputs from tributaries; therefore, any change in operational flexibility is likely muted and negligible by the time water from the reservoir reaches the intertidal zone so there would be no impact.

Ogier Ponds CM Operations

The most downstream extent of the Ogier Ponds CM is over 25 ~~20~~ miles upstream of the tidally influenced portion of Coyote Creek; therefore, no impacts from Ogier Ponds CM operations are predicted for longfin smelt However, enhanced sediment transport and conveyance of freshwater downstream to the intertidal zone may benefit longfin smelt because the species is thought to have better reproductive success when there is increased sediment, which provides cover for emergent larvae and juveniles (Rosenfield 2010, Lewis et al. 2020). These improvements could support a larger and more resilient longfin smelt population and, with respect to adverse impacts, there would be no impact.

North Channel Reach ~~Extension~~ Operations

Longfin smelt would benefit from enhanced passage of geomorphic flows as were described for steelhead which include the potential to release up to 6,000 cfs through the improved outlet and maintained North Channel Reach ~~Extension~~. ~~Improved conveyance~~ Conveyance of freshwater downstream of that magnitude to the intertidal zone compared to Pre-FERC Order Conditions may benefit longfin smelt in years that it is activated because the species is thought to have better reproductive success when there is more freshwater input, which provides high densities of food items for emergent larvae and juveniles (Rosenfield 2010, Lewis et al. 2020). These improvements would support a larger and more resilient longfin smelt population in years that it is activated, and, with regard to adverse impacts, there would be no impact on longfin smelt.

Spawning Gravel and Rearing Habitat Enhancements in the Live Oak Restoration Reach and Sediment Augmentation Program

The CWMZ is located over 25 ~~20~~ miles upstream from the tidally influenced portions of Coyote Creek Watershed. Longfin smelt do not occur within or near the CWMZ. Therefore, Spawning Gravel and Sediment Augmentation Program Maintenance activities are predicted to have no direct impact on longfin smelt individuals. However, placement of sediment has the potential to degrade water quality downstream of the work area if gravels and associated fine sediment enter the stream. However, the species is not present near the placement or later gravel mobilization by high flows so there would be no direct impact from placement of the gravels and sediment. Also, when flows are high enough to mobilize the sediment in the sediment augmentation piles, but there would already be elevated background levels of suspended sediment; therefore, additional sediment from the piles would not add substantially to the total sediment that is already suspended during high flows.

As previously described, longfin smelt spawning appears to occur near the fresh-salt water mixing zone (Rosenfield 2010) and if the species spawn in Coyote Creek, it is likely in the intertidal portion of the creek. It is assumed the longfin smelt can tolerate some levels of suspended sediment during their incubation period. Therefore, water quality and sediment impacts on Coyote Creek watershed and intertidal areas would not affect spawning longfin smelt. In addition, the BMPs and AMMs discussed in the impact analysis for steelhead will minimize water quality impacts as previously discussed. Further, noticeable effects of sediment or water quality impacts due to maintenance are not anticipated given the distance from the construction footprint to the tidally influenced portions of Coyote Creek (over <u>25</u> ~~20~~ miles). As discussed previously, it is likely longfin smelt tolerate and even seem to prefer turbid water with relatively high suspended sediment so no impacts on longfin smelt are predicted from the sediment and gravel augmentation programs.

In addition, increased sediment transport downstream of the construction footprint may benefit the health of South San Francisco Bay, which would benefit native species in the area, including longfin smelt. Increased sediment transport from the gravel and sediment augmentation programs would result in more inorganic material than would otherwise be transported. Within the San Francisco Bay, this century, supplementary sediment sources will be required to allow tidal marshes and mudflats to gain elevation faster than projected sea-level rise (Dusterhoff et al. 2021). These environments are crucial to the health of the Bay and support endangered species, provide nutrients that benefit aquatic species, and purify the surface water discharging into Francisco Bay (Dusterhoff et al. 2021); therefore, with respect to adverse impacts there would be no impact.

Phase 2 Coyote Percolation Dam CM Operations

The Coyote Percolation Dam is ~~over 17~~ <u>approximately 22 stream</u> miles upstream of the tidally influenced portions of Coyote Creek, so operation of the dam would have no impact on longfin smelt.

Project and FAHCE Adaptive Management

As discussed for the previous fish species, refinements under the AMP would likely have impacts similar to those discussed in this EIR under Conservation Measures Construction but at a much smaller scale for Ogier Ponds and the Coyote Percolation Dam. Therefore, there would be no impact on longfin smelt.

Under the AMP, there would be compliance monitoring, validation monitoring, <u>effectiveness monitoring,</u> and a long-term trend monitoring program however all monitoring would occur in areas where longfin smelt do not occur so there would be no impact on longfin smelt from these monitoring activities.

The post-construction operations flow releases from Anderson Dam may be modified to achieve geomorphic function of the river system via floodplain inundation, spawning gravel maintenance, and channel formation. Improved geomorphic flows in conjunction with the continued maintenance of the Live Oak Restoration Reach together with the Sediment Augmentation Program (Section *2.6.3 Sediment Augmentation Program*) would address historical blockage of sediment by Anderson Dam and Reservoir restoring more natural geomorphic processes downstream of the dam benefiting longfin smelt and their habitat.

Significance Conclusion Summary for Longfin Smelt

The only components of the Project that could impact longfin smelt and their habitat would be the increased sediment transport to the intertidal reaches of Coyote Creek during Seismic Retrofit construction, and this impact would be **less than significant**. Increased sediment transport may benefit longfin smelt in both the short-term and long-term.

Mitigation Measures

No mitigation is required.

Impact FR-1g: White Sturgeon **(Less than Significant)**

Seismic Retrofit Construction

Seismic Retrofit Construction Activities

White sturgeon have been observed in the study area but only occur in the tidally influenced areas of Coyote Creek and not in the freshwater portions of Coyote Creek (Otolith Geochemistry & Fish Ecology Laboratory 2021, 2022, 2023). White sturgeon spawning occurs in the Sacramento River and is not documented to occur in Coyote Creek or other tributaries of its stature (Zeug et al. 2014, D. Salsbery, personal communication, as cited in Buckmaster and Hobbs 2009). The Seismic Retrofit construction footprint is located ~~over 25~~ <u>approximately 32 stream</u> miles upstream from the tidally influenced portions of Coyote Creek Watershed. White sturgeon do not occur within or near the Seismic Retrofit construction footprint. ~~.~~Therefore, Seismic Retrofit construction activities within or near the construction footprint are predicted to have no direct impact on white sturgeon individuals or their habitat.

Seismic Retrofit (Anderson Dam) and Instream Flows Operations during Seismic Retrofit Construction

White sturgeon spawning occurs in the Sacramento River and is not documented to occur in Coyote Creek (Zeug et al. 2014, D. Salsbery, personal communication, as cited in Buckmaster and Hobbs 2009). Therefore, sediment transported during the Project in the Coyote Creek watershed and intertidal areas would not affect spawning white sturgeon.

Little scientific literature exists regarding the effects of suspended sediment on other life stages of white sturgeon. It is likely white sturgeon have similar suspended sediment tolerances to Atlantic sturgeon (*Acipenser oxyrinchus oxyrinchus*); the effects of suspended sediment on juvenile Atlantic sturgeon are minimal when individuals have the opportunity to escape conditions mimicking dredging operations (Wilkens et al. 2015). Sediment increases at the mouth of Coyote Creek during Seismic Retrofit construction activities, such as drawdown and bypass flows would be temporary and any white sturgeon in the area would be able to behaviorally regulate their exposure by swimming to another area of the San Francisco Bay or can handle the level of sediments that are present so there would be less-than-significant impacts on white sturgeon from sediment concentrations in instream flows during construction. In addition, it is likely white sturgeon have high tolerances to suspended sediment and increased sediment transport may benefit habitat in South San Francisco Bay. In the long term, inorganic sediment inputs to San Francisco Bay may benefit white sturgeon for the same reasons outlined for longfin smelt. Therefore, there would be no short-term or long-term impact from Anderson Dam construction activities or instream flow operations during Seismic Retrofit construction.

Conservation Measures Construction

The following Conservation Measures, Normal Operation of Coyote Reservoir, Construction Period Imported Water Releases, and the Operation of Chillers, do not have a construction component and would not impact white sturgeon.

Conservation Measures that require construction: Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, Maintenance of Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach, Sediment Augmentation Program, Phase 2 Coyote Percolation CM would have no impact on white sturgeon as this species only occurs in the tidal reaches and construction related impacts will not be of a magnitude that will reach that portion of the system. See the reasons outlined for longfin smelt for additional detail.

Construction Monitoring Impacts Analysis

White sturgeon would not be present in the locations where monitoring activities that would affect the channel would occur; therefore, there would be no impact on white sturgeon from construction monitoring.

Post-Construction Instream Flows Operations (FAHCE Rule Curves)

White sturgeon spawning occurs in the Sacramento River and is not documented to occur in Coyote Creek (Zeug et al. 2014, D. Salsbery, personal communication, as cited in Buckmaster and Hobbs 2009). Therefore, there would be no effects of the Project on white sturgeon spawning habitat. White sturgeon likely use only the tidally influenced reaches of Coyote Creek, if any areas, for rearing and foraging. As described for longfin smelt, the tidally influenced areas are ~~over 25~~ approximately 32 stream miles from Anderson Dam and releases and potential changes in salinity are unlikely to cause any meaningful effects on white sturgeon or their habitat.

Therefore, there would be no impact from post-construction operations (FAHCE rule curves) on rearing and foraging white sturgeon.

Post-Construction Seismic Retrofit and Conservation Measures Operations, Maintenance, and Adaptive Management

White sturgeon spawning occurs in the Sacramento River and is not documented to occur in Coyote Creek (Zeug et al. 2014, D. Salsbery, personal communication, as cited in Buckmaster and Hobbs 2009). Therefore, there would be no effects of the Project's post-construction operations, maintenance, and monitoring on white sturgeon spawning habitat. White sturgeon likely use the tidally influenced reaches of Coyote Creek for rearing and foraging.

Due to their same occurrence in the intertidal areas of Coyote Creek and Alviso Slough, there would be no impact from Seismic Retrofit and Conservation Measures Construction or Post-Construction Operations, Maintenance, and Monitoring on rearing and foraging white sturgeon for the same reasons outlined for longfin smelt. Project and FAHCE Adaptive Management.

White sturgeon spawning occurs in the Sacramento River and is not documented to occur in Coyote Creek (Zeug et al. 2014, D. Salsbery, personal communication, as cited in Buckmaster and Hobbs 2009) and only occur in the tidally influenced reaches of Coyote Creek. Therefore, there would be no potential effects of the Project adaptive management on white sturgeon habitat.

Due to their same occurrence in the intertidal areas of Coyote Creek and Alviso Slough, there would be no impact from the Project and FAHCE AMP, and there would be likely long-term benefits for rearing and foraging white sturgeon for same reasons outlined for longfin smelt.

Significance Conclusion Summary for White Sturgeon

The only components of the Project that could impact white sturgeon and their habitat would be the increased flow and sediment transport to the intertidal reaches of Coyote Creek and Alviso Slough during Seismic Retrofit construction. In the short-term, there would **less-than-significant impacts** on white sturgeon from increased sediment transport and, in the long-term, the Project may benefit white sturgeon.

Mitigation Measures

No mitigation is required.

Impact FR-1h: Green Sturgeon (Southern Distinct Population Segment) (No Impact)

Green sturgeon do not spawn in the study area, so there would be **no impacts** to spawning green sturgeon from the Project. Green sturgeon could occur in the study area during rearing and foraging, but their occurrence is not documented in the study area or even in close proximity to the study area to Valley Water’s knowledge despite being designated critical habitat. Because their occurrence seems to be extremely rare or non-existent in the study area, there would be no adverse impacts to green sturgeon, but there may still be the same benefits to green sturgeon habitat for the same reasons outlined for longfin smelt and white sturgeon from increased sediment transport transferring inorganic sediment to San Francisco Bay.

Mitigation Measures

No mitigation is required.

Impact FR-1i: Riffle Sculpin (Less than Significant)

Seismic Retrofit Construction

Seismic Retrofit Construction Activities

Riffle sculpin occur in Upper Penitencia Creek (Moyle and Campbell 2022) and are not expected to occur in Coyote Creek mainstem at or downstream of the Seismic Retrofit construction footprint; therefore, no impacts or benefits on riffle sculpin from Seismic Retrofit construction activities would occur.

Seismic Retrofit (Anderson Dam) and Instream Flow Operations during Seismic Retrofit Construction

Riffle sculpin do not occur in Coyote Creek downstream of the construction footprint. Therefore, instream flow operations during Seismic Retrofit construction activities would not affect flow magnitudes, temperatures, DO, or sediment transport in riffle sculpin habitat. Instream flow operations during construction would have no impacts or benefits for riffle sculpin individuals or habitat.

Conservation Measures Construction

Riffle sculpin are not expected to occur in Coyote Creek at or downstream of the locations of each conservation measure; therefore, there would be no impacts or benefits for riffle sculpin from Conservation Measure construction.

Construction Monitoring

The only cause of Project impacts on riffle sculpin would be from non-native species or diseases transferred from Coyote Creek to Upper Penitencia Creek during implementation of the Fish Rescue and Relocation Plan, which could result in the relocation of *O. mykiss* from Coyote Creek to Upper Penitencia Creek if necessary. The relocation could result in the transfer of non-native species or pathogens to Upper Penitencia Creek either via vehicles and equipment or from the fish themselves. Introduction of non-native species or novel pathogens to Upper Penitencia Creek could cause more pathology, disease, predation, or competition for riffle sculpin.

However, in 2020, *O. mykiss* were rescued from Coyote Creek and relocated to Upper Penitencia Creek during a fish rescue and relocation effort (Valley Water 2021c ~~2021h~~). Valley Water implemented a “triple rinse” of relocated O. mykiss to aid with acclimation, as well as to ensure that no water from Coyote Creek entered Upper Penitencia Creek. Valley Water sampled eDNA at the sites from which *O. mykiss* were rescued from in Coyote Creek and the sites *O. mykiss* were relocated to in Upper Penitencia Creek in May and September of the year following the relocation effort for amphibian pathogens Bd, Bsal and ranavirus. Relocation sites on Upper Penitencia Creek were visually surveyed for New Zealand Mud Snails (NZMS) and eDNA samples were collected and analyzed for NZMS DNA in May and September following the fish rescue and relocation effort. No new pathogens attributable to fish relocation or new non-native species introductions were observed or detected (Valley Water 2022c ~~2021j~~).

Based on data collection during existing conditions regarding steelhead presence in the FWCMZ, it is suggesting that *O. mykiss* were able to persist despite temperatures above optimal in the late summer and early fall (Valley Water 2022). Therefore, future relocations of *O. mykiss* to Upper Penitencia Creek are less likely to occur, but if they do occur, given the low likelihood of relocation and the low likelihood of introduced species or diseases that do not already exist in Upper Penitencia Creek, impacts to riffle sculpin from Construction Monitoring would be less than significant.

Post-Construction Instream Flows Operations (FAHCE Rule Curves)

Riffle sculpin have not been observed in Coyote Creek downstream of Anderson Dam but are found in Upper Penitencia Creek. There would be no Project impact associated with implementing the FAHCE rule curves.

Post-Construction Seismic Retrofit and Conservation Measures Operations, Maintenance, and Adaptive Management

Riffle sculpin occur in Upper Penitencia Creek (Moyle and Campbell 2022) and are not expected to occur in Coyote Creek mainstem at or downstream of Anderson Dam, where all post-construction monitoring and maintenance activities that were previously described in the steelhead and Chinook salmon equivalent sections that were covered by the DMP, SMP, and PMP occur. Therefore, no impacts or benefits are predicted for riffle sculpin from the post-construction monitoring and maintenance activities.

Anderson Dam Post-Construction Operations

Riffle sculpin occur in Upper Penitencia Creek (Moyle and Campbell 2022) and are not expected to occur in Coyote Creek mainstem at or downstream of Anderson Dam; therefore, no impacts or benefits are predicted for riffle sculpin from Anderson Dam post-construction operations.

Ogier Ponds CM Operations

Riffle sculpin have not been observed downstream of Anderson Dam in Coyote Creek. As they are located in Upper Penitencia Creek, there would be no impact from Ogier Ponds CM operations.

North Channel ~~Extension~~ Operations

Riffle sculpin have not been observed downstream of Anderson Dam in Coyote Creek. As they are located in Upper Penitencia Creek, there would be no impact from Maintenance of the North Channel Reach ~~Extension~~ operations.

Maintenance Activities at the Live Oak Restoration Reach and Sediment Augmentation Program

Riffle sculpin have not been observed downstream of Anderson Dam in Coyote Creek. As they are located in Upper Penitencia Creek, there would be no impact from spawning gravel and rearing habitat enhancements or the Sediment Augmentation Program.

Phase 2 Coyote Percolation Dam CM

Riffle sculpin have not been observed downstream of Anderson Dam in Coyote Creek. As they are located in Upper Penitencia Creek, there would be no impact from Phase 2 Coyote Percolation Dam CM operations and maintenance.

Project and FAHCE Adaptive Management

Riffle sculpin have not been observed downstream of Anderson Dam in Coyote Creek and only occur in Upper Penitencia Creek in the study area, so there would be no impacts from Adaptive Management or geomorphic flows, which is related to Coyote Creek under the FAHCE Program for steelhead and Chinook salmon.

Significance Conclusion Summary for Riffle Sculpin

The only cause of impacts on riffle sculpin would be from invasive species or disease transferred from Coyote Creek to Upper Penitencia Creek from the Fish Rescue and Relocation Plan. As discussed in the impact assessment, future relocation to Upper Penitencia Creek is unlikely and impacts would be **less than significant** if it were to occur.

Mitigation Measures

No mitigation is required.

3.4.5 Cumulative Impacts

The geographic study area for fisheries resources encompasses the Coyote Creek watershed downstream of Coyote and Anderson Dams, the Upper Penitencia Creek watershed, and South San Francisco Bay.

This section describes the Project's contribution to cumulative impacts on fisheries resources, as summarized in **Table 3.4-12.**

Cumulative impact thresholds for fisheries resources are the same as the impact thresholds presented in Section 3.4.3.6 ~~3.4.4~~, *Thresholds of Significance*.

Table 3.4-12. Summary of Project Impact Contribution to Cumulative Impacts on Biological Resources – Fisheries Resources

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact FR-1: Have a substantial adverse effect, either directly, through habitat modifications, or through substantial interference with movement on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW, NMFS, or USFWS in the fisheries resources study area	No	No	NCC	None	No

Cumulative Impact FR-1: Have a substantial adverse effect, either directly, through habitat modifications, or through substantial interference with movement on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW, NMFS, or USFWS in the fisheries resources study area (Not Cumulatively Considerable)

The Project's impact on special-status fisheries resources, including CCC steelhead, Chinook salmon, Pacific lamprey, Sacramento hitch, southern coastal roach, longfin smelt, white sturgeon, green sturgeon (Southern DPS), and riffle sculpin, would be less than significant in the short-term and less than significant or beneficial in the long-term for all stages of the Project.

The Project would result in certain construction phase impacts to these fisheries resources from Seismic Retrofit Construction; Conservation Measures Construction; and Construction Monitoring. In the post-construction phase, there would also be some impacts from Anderson Dam and Conservation Measures monitoring and maintenance; Instream Flows Operations (FAHCE rule curves); and the Project and FAHCE AMP. These impacts would be less than significant. These impacts would be reduced through BMPs, VHP conditions, and Project Conservation Measures.

The Project would benefit fisheries resources over the long-term through Seismic Retrofit Construction and Post-Construction Operations, Monitoring, and Maintenance; Conservation Measures Construction and Post-Construction Operations, Monitoring, and Maintenance; Construction Monitoring; Post-Construction Instream Flows Operations (FAHCE rule curves); and the Project and FAHCE AMP. Benefits to fisheries resources include increased, restored, and enhanced habitat, improved and increased passage conditions, improved rearing conditions, all of which support larger and more resilient populations of steelhead and Chinook salmon. Post-Construction Flow Operations are specifically designed to enhance conditions for steelhead and Chinook salmon and all these actions will be further adapted to benefit the species through the AMP process.

Possible impact mechanisms on longfin smelt, white sturgeon, and green sturgeon would be increased flow and sediment transport to the intertidal reaches of Coyote Creek and Alviso Slough during the Project. Longfin smelt could also be affected by salinity changes during the Project in intertidal areas compared with Pre-FERC Order Baseline Conditions. Post-Construction Instream Flows Operations (FAHCE rule curves) would not affect estuarine species such as longfin smelt, green sturgeon, and white sturgeon, as the magnitude and duration associated with changes in flow regimes are muted due to the distance between the dam release point and the habitat these fish are using. Conservation Measures Construction and Post-Construction Operations, Monitoring, and Maintenance; Construction Monitoring also are occurring in the reaches upstream of the habitat these species use, so no adverse impact is to occur during these actions. Seismic Retrofit Construction and Post-Construction Operations, Monitoring, and Maintenance; Conservation Measures Construction and Post-Construction Operations, Monitoring, and Maintenance; Construction Monitoring; Post-Construction Instream Flows Operations (FAHCE rule curves); and the Project and FAHCE AMP would not affect riffle sculpin as these actions do not take place in Upper Penitencia Creek. Invasive species or disease transferred from Coyote Creek to Upper Penitencia Creek from the FERC Ordered Fish Rescue and Relocation could affect riffle sculpin. However, none of these Project-related impacts would exceed the identified thresholds of significance as risk of transfer is low and BMPs and monitoring are in place to reduce said risks.

Overall, adverse impacts on fisheries resources would be periodic and temporary, and less than significant during the construction phase. The Project would benefit fisheries resources in the long term through increased and enhanced habitat supporting a larger and more resilient fish populations. The overall impact is less than significant.

Cumulative Effects of Project with the FOCP

The FOCP would involve modifications to the existing structures surrounding Anderson Dam and Reservoir, some of which could benefit fisheries ~~resources~~. The construction schedules for FOCP and Project would not overlap, reducing the potential intensity of ~~for~~ cumulative construction-related impacts. Also, the FOCP includes AMMs and a Habitat Mitigations and Monitoring Plan (HMMP), designed to minimize impacts on fish populations and habitats. The FOCP also includes the North Channel Extension, which would benefit fisheries resources by decreasing stranding risk from the existing backwater in the North Channel and decrease warm ponded water that promotes habitat for non-native piscivores. This would allow higher conveyance of flows through the North Channel which will protect the South Channel habitat enhancements, and allow for future geomorphic flows from the Geomorphic Flows Plan (a component of the Project). This would promote better geomorphic function of Coyote Creek expected to support native fish species (steelhead, Chinook salmon, Pacific lamprey, Sacramento hitch, southern coastal roach, longfin smelt, and white sturgeon) and limit non-native species.

The drawndown reservoir may contribute to cumulative temperature impacts on steelhead prior to installation of chillers. Despite the delay in the delivery of the chillers resulting from supply chain issues beyond Valley Water's control, *O. mykiss* have persisted at various age classes and in good body condition in Coyote Creek for three years of FOCP construction in the absence of chillers, including during extreme drought conditions characterizing 2 of those 3 years of construction.

Also, two fish rescues have been conducted under FOCP according to the Fish Rescue and Relocation Plan approved by NMFS resulting in the total capture of 235 and relocation of 121 *O. mykiss* (Valley Water 2021c). During these rescues, Valley Water documented mortality of four individual *O. mykiss* (less than 2 percent of captured *O. mykiss*).

The FOCP combined with the Project would therefore not cause significant cumulative impacts on fisheries, and the Project's contribution would be not cumulatively considerable. Combined with the FOCP, the Project would provide long term benefits to steelhead, Chinook salmon, Pacific lamprey, Sacramento hitch, southern coastal roach, longfin smelt, and white sturgeon.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Cumulative projects, plans, and programs, such as Valley Water's other seismic retrofit, dam improvement, and flood protection projects, could result in incrementally adverse impacts if their construction or operational timeframes overlap. The reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, when combined with impacts of the Project, have the potential to have a substantial adverse effect, either directly, through habitat modifications, or through substantial interference with movement on any fish species identified as a candidate, sensitive, or special-status species in the study area. Future projects such as Valley Water's other seismic retrofit, dam improvement, and flood protection projects; the San Francisco Bay Shoreline Protection Project; and various non-Valley Water development projects could adversely affect fisheries resources through mechanisms such as changes to aquatic habitats, including water temperature and flows, degradation of water quality, and increased sedimentation. However, future projects, such as FAHCE, SMP, the Encampment Clean Up Program, Valley Water restoration projects, and the Santa Clara Valley Habitat Restoration Program would have long-term beneficial effects on fisheries resources in the cumulative study area through improvements to fish habitat, including changes in the amount and timing of flows, maintaining the migration corridor, and improved water quality. Programs such as SMP and Valley Water restoration projects are or would be managed under state and federal permits with permit conditions that outline necessary avoidance and minimization measures and mitigation measures to protect resources. These conditions would reduce impacts and further reduce any cumulative effects. Because some of the future projects could result in adverse effects to fisheries resources, the Project, in combination with these other probable future projects within the study area, could have a short-term cumulative impact on fisheries resources, with long-term benefits, and the overall cumulative impact on fisheries resources would be less than significant.

Significance Conclusion Summary

The Project, FOCP, and most other probable future projects have the potential to affect fisheries resources through a variety of mechanisms during construction and/or long-term. As summarized above, the Project would result in certain construction phase impacts on fisheries resources from Seismic Retrofit Construction; Conservation Measures Construction; and Construction Monitoring. These impacts will be reduced <u>and offset</u> through BMPs, VHP conditions, and Project Conservation Measures. In the post-construction phase, there would also be some minor impacts from Anderson Dam and Conservation Measures monitoring and maintenance. Post-Construction Instream Flows Operations (FAHCE rule curves); and the Project and FAHCE AMP. These impacts would be less than significant. Other probable projects are managed under state and federal permits and impacts to species would be reduced in accordance to these regulations, thus reducing any cumulative impacts.

The Project would benefit fisheries resources over the long-term through Seismic Retrofit Construction and Post-Construction Operations, Monitoring, and Maintenance~~,~~; Conservation Measures Construction and Post-Construction Operations, Monitoring, and Maintenance; Construction Monitoring; Post-Construction Instream Flows Operations (FAHCE rule curves) and the Project and FAHCE AMP. These actions would result in increased and improved habitat conditions benefiting or having no adverse effect on fish resources within the project area. Also, through the Project and FAHCE AMP, adaptive actions would be implemented when AMP measurable objectives are not being met, which would reduce any cumulative impacts that may arise during Project implementation.

Adverse impacts on steelhead and other special-status fish species would be periodic and temporary, would be reduced through BMPs, VHP conditions, and Project Conservation Measures, and would be less than significant during the construction phase. The Project would benefit steelhead in the long-term through increased and enhanced habitat, and management supporting a larger and more resilient steelhead population. As a result, the Project's contribution to cumulative impacts to fisheries resources is **not cumulatively considerable.**

Mitigation Measures

No mitigation is required.

3.5 Biological Resources—Wildlife and Terrestrial Resources

This section presents the environmental setting, regulatory setting, and impacts of the Project related to terrestrial biological resources (i.e., plants, animal species (excluding fish), land cover types, and sensitive and regulated habitats), including all biological resources, except fisheries. The *CEQA Guidelines* significance criteria for such resources address impacts related to special-status species and their habitats, sensitive communities, federally and State-regulated wetlands and other waters, wildlife movement and native wildlife nursery sites, conflicts with local policies, and conflicts with adopted HCPs.

The study area used to assess impacts on terrestrial biological resources consists of areas that may be affected as a result of the Project. The study area is depicted on **Figure 3.5-1**. The study area includes the Project Area, which consists of the footprints of all construction activities at the dam and the entire Anderson Reservoir bed (the Seismic Retrofit Area), and the footprints of conservation activities associated with the Project (the Conservation Measures Project Area), including the Ogier Ponds CM, the Coyote Percolation Dam CM, and Coyote Creek from Anderson Dam downstream to the Coyote Percolation Dam CM Areas. The study area also includes areas referred to herein as the “expanded study area”, consisting of nearby areas and areas along Coyote Creek and in San Francisco Bay downstream from Project activities that would be impacted by Project activities, as indicated on **Figure 3.5-1**; that figure includes labels for areas that are discussed later in this section as being included in the expanded study area.

Figure 3.5-1. Terrestrial Biological Resources Study Area

Anderson Dam Seismic Retrofit Project EIR (3403-06)
February 2023

3.5.1 Environmental Setting

To identify existing biological conditions in the study area, a number of information sources were reviewed, including the following:

- Documents prepared for the FOCP (Horizon 2020, Valley Water 2020a ~~2020c~~, 2020b ~~2020d~~), and USFWS consultation on the FOCP (USFWS 2020)
- Documents prepared for Valley Water's evaluation of its DMP (Valley Water 2008, 2012a)
- Documents prepared for Valley Water's SMP ~~2 Update~~ (Valley Water 2011a ~~2011b~~, 2011c ~~2021b~~, 2019a), and the USFWS Biological Opinion on the SMP ~~2~~ (USFWS 2014)
- The Ogier Ponds Feasibility Study (Valley Water 2018a)
- The VHP (ICF 2012)
- Data on special-status species occurrences (Bousman 2007a, Shuford and Gardali 2008, California Natural Diversity Data Base [CNDDB] 2022)
- California Rare Plant Ranks (CRPR; formerly known as California Native Plant Society [CNPS] lists; CNPS 2022) and applicable records
- *The Jepson Manual,* Second Edition (Baldwin et al. 2012)
- Reports on the results of numerous surveys and assessments performed by Valley Water and its consultants, including the following:
  - Habitat/land cover mapping for the FOCP (Horizon 2020), refined through 2022 to include habitats in additional areas
  - Delineation of potential waters of the U.S. in the Anderson Dam area performed for the DMP (Valley Water 2008) and FOCP (Valley Water 2020b ~~2020d~~), and in additional areas from 2013 to 2022 as the Project Area has been refined (Valley Water ~~2022c~~ 2024b)
  - Reconnaissance-level surveys of the Project Area for wildlife species and their habitats, conducted on numerous occasions from 2013 to 2022
  - Surveys for the plant pathogen *Phytophthora* around Anderson Dam and Anderson Reservoir to inform planning, impact assessment, and Conservation Measures to protect sensitive plant species and vegetative communities from the spread of *Phytophthora* (Phytosphere Research 2018~~; 2022~~)
  - Protocol-level surveys for special-status plants in 2006 and 2008 as part of Valley Water's evaluation of its DMP (Valley Water 2012a), the FOCP, and Project in 2013 and 2014 (Valley Water 2014a, 2014b) and in 2017, 2018, and 2021 (Valley Water 2021a ~~2021f~~)
  - Monitoring of a San Francisco collinsia (*Collinsia multicolor*) population on an eroding serpentine slope along the shoreline of Anderson Reservoir, since it was discovered by a Valley Water botanist in 2009 ~~(Valley Water 2012d),~~ including annual surveys of the abundance and distribution of this population through 2022
  - A survey for adult Bay checkerspot butterflies conducted in April 2014, in compliance with the VHP, in all areas of the Project Area providing potential habitat for the species

- A survey of the Anderson Dam area for milkweed (*Asclepias* spp.), the larval hostplant of the monarch butterfly, conducted in 2021 (Valley Water 2021b) and a reconnaissance survey for special-status bumblebees conducted at Anderson Reservoir in July 2022
- Annual fiber-optic scoping inspections, from 2010 to 2013, of all burrows on both faces of Anderson Dam to determine whether California tiger salamander, California red-legged frog, or other special-status species were present in those burrows prior to the burrows' destruction (Valley Water 2010a, 2011b ~~2011a~~, 2012d ~~2012c~~, 2013 ~~2013c~~)
- A reconnaissance-level survey and habitat assessment for special-status amphibians and reptiles, including the California tiger salamander, California red-legged frog, foothill yellow-legged frog, and northwestern pond turtle, conducted in 2016 in areas to be monitored, in accordance with VHP conditions, for effects of dewatering associated with the Project (Valley Water 2016); focused surveys for those species conducted in those monitoring areas in 2019 (Valley Water 2019b ~~2019e~~); and numerous preactivity surveys for these species performed prior to geotechnical investigations for the Project, around Anderson Dam, and in the unlined portion of the spillway, from 2014 to 2022 (e.g., Valley Water 2020c ~~2020b~~)
- Monitoring for northwestern pond turtle performed for the FOCP in Anderson Reservoir and along Coyote Creek downstream to the Coyote Percolation Pond in 2021 and 2022, in accordance with the FOCP western pond turtle monitoring plan (Valley Water 2020d ~~2020i~~)
- Habitat surveys for the tricolored blackbird conducted at various locations around Anderson Dam, Anderson Reservoir, and along Coyote Creek between Anderson Dam and the Coyote Percolation Dam in 2013, 2017, 2018, and 2022
- Surveys for nesting bald eagles and golden eagles in the vicinity of Anderson Reservoir, with informal surveys in 2018 and early 2019 (Valley Water 2019c ~~2019b~~), a single aerial survey in May 2019 (Valley Water 2019d ~~2019c~~), and intensive surveys from the ground and by helicopter during the 2020, 2021, and 2022 breeding seasons (Valley Water 2020e ~~2020a~~, 2021c ~~2021e~~, 2022a ~~2022b~~)
- A focused 2017 survey for ringtails at Basalt Hill, using bait stations and motion-sensor cameras, as well as genetic analysis of scat (Valley Water 2017)
- Monitoring surveys at a pallid bat (*Antrozous pallidus*) colony in a barn along Cochrane Road (hereafter "Cochrane Road barn") near the base of Anderson Dam, in 2019, 2021, and 2022 (Valley Water 2019e ~~2019d~~, 2021d)

3.5.1.1 Existing Land Cover Types, Natural Communities, and Habitats

Based on dominant plant species and general community composition, the Seismic Retrofit Project Area supports 15 land cover types, natural communities, and habitats, defined and named in accordance with VHP conventions and hereafter referred to as "land cover types" per the VHP. The distributions of these land cover types are depicted on **Figure 3.5-2** and **Figure 3.5-3** for the Seismic Retrofit, ~~**Figure 3.5-3**~~ **Figure 3.5-4** for the Ogier Ponds CM, **Figure 3.5-5** for the Coyote Percolation Dam CM, **Figure 3.5-6** for the North Channel Reach ~~Extension Area~~ and ~~the~~ Live Oak Restoration Reach maintenance areas, and **Figure 3.5-7** for the remainder of Coyote Creek between the Seismic Retrofit Coyote Percolation Dam CM Area.

Figure 3.5-7. Coyote Creek (Anderson Dam to Coyote Percolation Dam) Land Cover Map
Anderson Dam Seismic Retrofit Project EIR (3403-06)
August 2024

The acreages of these land cover types within the Seismic Retrofit Area, Ogier Ponds CM Area, ~~and~~ Coyote Percolation Dam CM Area, and North Channel Reach and Live Oak Restoration Reach maintenance areas, are provided in **Table 3.5-1.** For perennial and intermittent streams, stream acreage is included in the acreage of mixed riparian woodland and forest, in accordance with VHP conventions, and the linear footage of streams in each of these Project Areas is provided in **Table 3.5-2**. The acreages/stream linear footage provided in these tables represent the extent of each land cover type within the footprint (i.e., potential impact area) of these Project components under baseline conditions.

Acreages of land cover types in the remainder of Coyote Creek between the Seismic Retrofit and Coyote Percolation Dam CM, as shown on **Figure 3.5-7**, are not summarized in **Table 3.5-1**, as no direct impacts are proposed in these areas. ~~Although Conservation Measures, including the Sediment Augmentation Program, are expected to occur somewhere in this segment of Coyote Creek, the locations and footprints of such Project activities within this area are not yet known.~~ An additional (15th) land cover type, Central California sycamore alluvial woodland, is present along this segment of Coyote Creek but not elsewhere in the Project Area.

In addition to these 15 land cover types, portions of the Seismic Retrofit, Ogier Ponds CM, and Coyote Percolation Dam CM Areas (summarized in the "Disturbed by FOCP" category in ~~(~~**Table 3.5-1**~~)~~ will have been impacted by the FOCP immediately prior to the commencement of the Seismic Retrofit. Permanent VHP impact fees will have been paid by Valley Water for areas that will have been permanently impacted by the FOCP. The CEQA baseline for construction impacts on terrestrial biological resources habitat conditions for the Seismic Retrofit and Conservation Measures construction (i.e., the Existing Conditions Baseline) is represented by existing conditions at the time of EIR preparation as modified by FOCP implementation (i.e., post-FOCP conditions). Initiation of Project construction would closely follow the completion of the FOCP, or at most, be separated by one wet season. As a result, when Project construction begins, much of the Project Area around Anderson Dam would have been recently disturbed by the FOCP. Vegetation present in disturbed upland (i.e., nonaquatic/wetland) areas, including riparian areas, would be likely to represent erosion-control seed mixes used to stabilize or winterize the FOCP-disturbed areas and would therefore be most similar to California annual grassland. Disturbed wetlands would still have wetland hydrology, but vegetation would not have had time to recover fully prior to Seismic Retrofit initiation. Portions of the FOCP impact area within Anderson Reservoir and within the Coyote Creek channel would represent the reservoir and perennial stream land cover types, respectively, but would have been recently disturbed by the FOCP. Because of the quick transition between the FOCP and commencement of the Seismic Retrofit, Valley Water would not have made an attempt to restore land cover types within areas of overlap between the two projects, so the conditions within those areas would either be developed ("urban-suburban") or some highly disturbed version of the underlying pre-FOCP land cover type that is no longer representative of a specific VHP land cover type when Seismic Retrofit activities commence. For these reasons, all areas that will have been disturbed by the FOCP and then would be subject to Project activities are represented by this "Disturbed by FOCP" land use category. However, the underlying pre-FOCP land cover types in these areas are depicted on **Figure 3.5-2** through **Figure 3.5-5**, in the areas overlaid by "FOCP Footprint" hatching. Also, because construction of the North Channel Extension as part of FOCP will result in changes in the location and extent of land cover types, the land cover types depicted on **Figure 3.5-6** and in **Table 3.5-1** reflect the type, location, and extent of land cover types in the North Channel Reach maintenance area as they are expected to be when ADSRP construction commences.

Table 3.5-1. Land Cover Types in the Seismic Retrofit, Ogier Ponds CM, Coyote Percolation Dam CM, North Channel ~~Extension~~ Reach, and Live Oak Restoration Reach Areas

Notes:

[1] In accordance with VHP conventions, acreages are reported to the nearest 0.1 acres except for wetland and riparian land cover types (and except where the acreage is very low).

~~[2] Acreages for the Live Oak Restoration Reach in this table do not include portions of that Conservation Measure that overlap the North Channel Extension (0.002 acres of intermittent stream, 0.02 acres of perennial stream, 0.001 acres of coastal and valley freshwater marsh, and 0.20 acres of mixed riparian woodland and forest) or Seismic~~

~~Retrofit Area (0.68 acres of perennial stream, 0.003 acres of coastal and valley freshwater marsh, 2.87 acres of mixed riparian woodland and forest, 3.5 acres of coast live oak forest and woodland, 0.1 acres of California annual grassland, and 0.6 acres of urban-suburban).~~

[~~3~~] ~~The "Total" column summarizes the total acreages within the Seismic Retrofit, Ogier Ponds CM, and Coyote Percolation Dam CM Areas. Additional impacts may result from Conservation Measures, such as the Sediment Augmentation Program, though the locations and extents of such impact areas are not yet known.~~

[34] A total of 357.6 acres of reservoir are present within the currently proposed Seismic Retrofit construction footprint, and an additional 849.2 acres are within additional areas within the reservoir where construction activities could potentially occur.

[3~~5~~] In addition to the 0.73 acres of perennial stream that will be impacted by Seismic Retrofit construction outside the FOCP footprint, 1.5 ~~1.98~~ acres that will have been temporarily impacted by the FOCP may be impacted by Seismic Retrofit construction as well.

[4~~6~~]*Portions of the Project Area in the "Disturbed by FOCP" category will have been impacted by the FOCP immediately prior to the commencement of the Seismic Retrofit, Ogier Ponds CM, and Coyote Percolation Dam CM. Permanent VHP impact fees will have been paid by Valley Water for impacts to the areas that will have been permanently impacted by the FOCP. The conditions within those areas will either be developed ("urban-suburban") or some highly disturbed version of the underlying pre-FOCP land cover type that is no longer representative of a specific VHP land cover type when Seismic Retrofit activities commence. Therefore, the Project baseline land cover type for these areas is not provided in* ***Table 3.5-1****. However, the underlying pre-FOCP land cover types in these areas are depicted on* ***Figure 3.5-2*** *through* ***Figure 3.5-5***, in the areas overlaid by "FOCP Footprint" hatching.

Key: CM = Conservation Measures; FOCP = Federal Energy Regulatory Commission Order Compliance Project

Table 3.5-2. Stream Linear Footage in the Seismic Retrofit, Ogier Ponds CM, ~~and~~ Coyote Percolation Dam CM, North Channel Reach ~~Extension~~, and Live Oak Restoration Reach Areas

Land Cover Type	Seismic Retrofit Area (linear feet)[1]	Ogier Ponds CM Area (linear feet)	Coyote Percolation Dam CM Area (linear feet)[2]	North Channel ~~Extension~~ Reach Area (linear feet)	Live Oak Restoration Reach (linear feet)[3]	Total (linear feet)[4]
Intermittent Stream	668 ~~864~~	0	0	678 ~~482~~	0	1,346
Perennial Stream	120 ~~1,082~~	2,020	584	470 ~~30~~	1,761	4.955 ~~5,477~~
Total	788 ~~1,946~~	2,0~~20~~	584	1,140 ~~512~~	1,761	6,301 ~~6,823~~

Notes:

[1] Totals for the Seismic Retrofit Area do not include approximately 1.3 ~~1.98~~ acres and 1,338 ~~1,674~~ linear feet of perennial stream that will have been impacted by the FOCP but that may also be present prior to the start of, and may therefore be impacted by, Seismic Retrofit construction.

[2] Totals for the Coyote Percolation Dam CM Area do not include approximately 65 linear feet of perennial stream that will have been impacted by the FOCP prior to the start of Coyote Percolation Dam CM construction.

~~[3] Linear footages for the Live Oak Restoration Reach in this table do not include portions of that Conservation Measure that overlap the North Channel Extension (17 linear feet of intermittent stream and 72 linear feet of perennial stream) or Seismic Retrofit Area (990 linear feet of perennial stream).~~

~~[4] The "Total" column summarizes the total linear footage of streams within the Seismic Retrofit, Ogier Ponds CM, and Coyote Percolation Dam CM Areas. Additional impacts may result from Conservation Measures, such as Sediment Augmentation Program, though the locations and extents of such impact areas are not yet known.~~

Key: CM = Conservation Measures

Habitat conditions, dominant plant species, and representative animal species for each of the 15 land cover types in the Project Area, as well as perennial and intermittent streams, are described in detail below. Special-status species are mentioned in the following land cover descriptions if they occur regularly in a given land cover type (as opposed to occurring infrequently); additional information on occurrences of special-status species, and those species' habitat associations, is provided in **Table 3.5-4** (for plants) and **Table 3.5-5** (for animals).

Reservoir

Habitat Conditions/Vegetation. Anderson Reservoir is an anthropogenic feature created from the impoundment of Coyote Creek. The reservoir is impounded by a compacted embankment dam made of earth and rock, which is approximately 240 feet high. The reservoir land cover type was mapped in all areas below the elevation of the reservoir's rim, which is 627.9 feet, equivalent to the spillway elevation. Currently, the water level in Anderson Reservoir is in a drawn-down condition, well below the height of its original design elevation due to DSOD and FERC restrictions. The exposed shoreline rim is rocky, steeply sloped, and sparsely vegetated in many areas, although some vegetation, including grasses, bull thistle (*Cirsium vulgare*), coyote brush (*Baccharis pilularis*), and Russian thistle (*Salsola tragus*), has become established in areas that have not recently been inundated. No substantial amounts of emergent vegetation are present in or around Anderson Reservoir.

The reservoir land cover type is also present within the Ogier Ponds CM Area; there, the larger impoundments (Ponds 1, 2, and 4 of the Ogier Ponds complex) were considered reservoir due to the large size and deep nature of these artificial waterbodies. Further downstream, the portion of the Coyote Percolation Pond immediately upstream from the Coyote Percolation Dam CM was also considered reservoir.

Wildlife. Common resident waterbirds that occur in and along the shoreline of Anderson Reservoir and the reservoir land cover types at the Ogier Ponds and Coyote Percolation Pond include the pied-billed grebe (*Podilymbus podiceps*), Canada goose (*Branta canadensis*), mallard (*Anas platyrhynchos*), American coot (*Fulica americana*), common merganser (*Mergus merganser*), and killdeer (*Charadrius vociferus*), among others. Shorebirds and wading birds, such as the greater yellowlegs (*Tringa melanoleuca*), spotted sandpiper *(Actitis macularius*), great egret (*Ardea alba*), snowy egret (*Egretta thula*), and others forage at the edges of the reservoir land cover type during migration and winter, and bald eagles forage for fish and waterfowl. Amphibian species that may breed in these reservoirs include the native western toad (*Anaxyrus boreas*), Sierran chorus frog (*Pseudacris sierra*), and the nonnative bullfrog (*Lithobates catesbeianus*). ~~Western~~ Northwestern pond turtles are also known to occur in this land cover type at the Ogier Ponds and Coyote Percolation Pond and have been reported from Anderson Reservoir (CNDDB 2022).

Pond

Habitat Conditions/Vegetation. The pond land cover type is present in the Seismic Retrofit Area in a small pool immediately below the concrete-lined spillway at Anderson Dam, and in portions of the Ogier Ponds CM area. The small pond below the concrete-lined spillway is lined with rock and supports no substantive vegetation. At the Ogier Ponds, the pond land cover type is represented by Pond 5, a groundwater-supported pond that is not in-line with Coyote Creek as Ponds 1 through 4 are. Pond 5 is a shallow pond ringed by cattails (*Typha* spp.) and other emergent vegetation. Along Coyote Creek between the Seismic Retrofit and Coyote Percolation Dam CM Areas, additional off-channel ponds occur at the Ogier Ponds and near Coyote Ranch.

Wildlife. Due to the small size of the pond downstream from the concrete-lined spillway at Anderson Dam, relatively few pond-associated wildlife species occur there. However, mallards, great blue herons (*Ardea herodias*), great egrets, and snowy egrets forage there, and western toads, Sierran chorus frogs, and bullfrogs are present. In addition to these species, pond habitats at the Ogier Ponds support a variety of waterfowl, including gadwall (*Mareca strepera*), cinnamon teal (*Spatula cyanoptera*), and double-crested cormorant (*Nannopterum auritum*). ~~Western~~ Northwestern pond turtles also occur occasionally in these pond habitats, though at the Ogier Ponds, they occur more abundantly in the reservoir land cover type.

Perennial Stream

Habitat Conditions/Vegetation. In the Project Area, perennial stream habitat is represented solely by Coyote Creek. Coyote Creek originates on Mount Sizer, located approximately 7 miles northeast of Anderson Dam, and flows through the western slope of the Diablo Range. At the base of the Diablo Range, the creek is impounded by two dams, first by Coyote Reservoir and then by Anderson Reservoir. Downstream of Anderson Reservoir the creek continues north from Morgan Hill into San José and empties into San Francisco Bay. In some areas, the perennial stream habitat supports perennial marsh vegetation (discussed separately in the coastal and valley freshwater marsh section below). Flow in the reach of Coyote Creek downstream of Coyote Dam and entering Anderson Reservoir is regulated by releases from Coyote Dam; these releases maintain perennial flows in the intervening reach. Downstream from Anderson Dam, flow is regulated primarily by releases from Anderson Dam. The perennial stream land cover type includes short segments of channel within the Ogier Ponds complex that carry water between reservoir/pond land cover types, as well as the reach of Coyote Creek within the Coyote Percolation Dam CM Area and Live Oak Restoration Reach.

Wildlife. Amphibians, such as the western toad, Sierran chorus frog, and bullfrog, are present in the perennial creek land cover type. The native northwestern pond turtle occurs in Coyote Creek, along with nonnative turtles that have been released locally from captivity, primarily red-eared sliders (*Trachemys scripta*). Waterbirds, such as the mallard, green heron (*Butorides virescens*), great egret, and belted kingfisher (*Megaceryle alcyon*), forage in the waters of perennial streams. Bats, including the Yuma bat (*Myotis yumanensis*) and big brown bat (*Eptesicus fuscus*), forage aerially on insects over these streams.

Intermittent Stream

Habitat Conditions/Vegetation. In the Seismic Retrofit Area, the intermittent stream land cover type is present within a channel between the waterfall downstream from the unlined portion of the Anderson Dam spillway and the North Channel of Coyote Creek, and within the North Channel itself.~~(including the North Channel Extension Area).~~ These areas experience wet-season flow, typically at very low rates unless Anderson Reservoir is spilling. The majority of intermittent stream channel bed is excavated bedrock (associated with previous quarrying activities at Chert Hill) with little soil development, and therefore vegetation is typically sparse. Water moves within a dispersed, finger-like network of smaller channels during low flow events. Only during reservoir spill releases is the entire channel filled with water. Further downstream, the North Channel of Coyote Creek is dominated by cobbles. Here the intermittent channel is underlain by riverwash and a riparian forest canopy grows along the channel up to the top of bank.

Wildlife. Water in the intermittent stream channel supports invertebrates, which attract foraging avian insectivores, such as flycatchers and swallows. Other birds, such as herons and egrets, may also forage along this channel as may common mammals, such as the raccoon (*Procyon lotor*).

Coastal and Valley Freshwater Marsh

Habitat Conditions/Vegetation. In the Seismic Retrofit Area, coastal and valley freshwater marsh occurs within the unlined portion of the Anderson Dam spillway and in very limited areas along the North Channel of Coyote Creek. Vegetation within this habitat is dominated by perennial aquatic emergent vegetation, such as cattails, and shoreline plants that grow along the edge of the aquatic habitat, such as iris-leaved rush (*Juncus xiphioides*), tall flatsedge (*Cyperus eragrostis*), fringed willow herb (*Epilobium ciliatum*), and fiddle dock (*Rumex pulcher*).

Coastal and valley freshwater marsh is present in several areas within the Ogier Ponds CM Area. There, large stands of coastal and valley freshwater marsh dominated by cattails and California bulrush (*Schoenoplectus californicus*) are present in the southwest portion of Pond 2 and around Pond 5, and small patches occur around the perimeter of Pond 1. Along Coyote Creek between the Seismic Retrofit and Coyote Percolation Dam CM Areas, coastal and valley freshwater marsh occurs in several additional areas, including areas downstream from the Coyote Creek Golf Course access road, upstream from Bailey Avenue, and near Coyote Ranch.

Wildlife. Freshwater marshes often provide habitat for a distinctive suite of wetland-associated wildlife species. Amphibians such as the native Sierran chorus frog and western toad, as well as the nonnative bullfrog, inhabit these wetlands. Avian species that nest and forage in adjacent riparian and oak woodland habitats forage in these wetlands. Common wetland-associated birds, such as the song sparrow (*Melospiza melodia*), red-winged blackbird (*Agelaius phoeniceus*), and common yellowthroat (*Geothlypis trichas*), nest and forage within these wetlands. Emergent wetlands at the Ogier Ponds provide nesting habitat for the American coot and common gallinule (*Gallinula galeata*) and foraging sites for herons and egrets.

Seasonal Wetland

Habitat Conditions/Vegetation. No seasonal wetland is present within the Seismic Retrofit Area or Coyote Percolation Dam CM Area. At the Ogier Ponds CM Area, seasonal wetland is represented by a small depressional area in the historical channel of Coyote Creek, just south of Pond 4 at the Ogier Ponds. This seasonal wetland is likely supported by high groundwater during the wet season and is dominated by annual beard grass (*Polypogon monspeliensis*). This wetland is shallow and does not pond for long periods, even during the wet season. Along Coyote Creek between the Seismic Retrofit and Coyote Percolation Dam CM Areas, additional seasonal wetlands occur in portions of the Ogier Ponds complex that are outside of the Ogier Ponds CM Area.

Wildlife. The seasonal wetland near the Ogier Ponds does not provide surface water long enough to support breeding amphibians or to provide aquatic foraging habitat for waterbirds. Although a variety of animals may drink or bathe in this wetland when surface water is present, the wildlife using this feature are primarily the species that occur in adjacent California annual grassland.

Mixed Riparian Woodland and Forest

Habitat Conditions/Vegetation. In the Seismic Retrofit Area, mixed riparian woodland and forest occurs along riparian corridors downstream of the Anderson Reservoir spillway and along Coyote Creek, including both the North and South Channels. This land cover type includes a variety of riparian shrubs and trees including arroyo willow (*Salix lasiolepis*), red willow (*Salix laevigata*), California sycamore (*Platanus racemosa*), bigleaf maple (*Acer macrophyllum*), and white alder (*Alnus rhombifolia*). These riparian tree species often co-occur with coast live oaks (*Quercus agrifolia*), and mixed riparian woodland and forest intergrades with coast live oak forest and woodland in some areas. The understory is composed of California blackberry (*Rubus ursinus*), California wildrose (*Rosa californica*), and other shrubs and herbaceous species along the banks.

Extensive mixed riparian woodland and forest is present in the Ogier Ponds CM Area along the historical Coyote Creek channel downstream from Barnhart Avenue, along the current Coyote Creek channel at the downstream end of the Ogier Ponds complex, in the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach, and in several locations around the pond and reservoir land cover types. Dominant plant species here include arroyo willow, red willow, California sycamore, and Fremont cottonwood (*Populus fremontii*). At the Coyote Percolation Dam CM Area, and along much of Coyote Creek between the Seismic Retrofit and Coyote Percolation Dam CM Areas, mixed riparian woodland and forest lines both sides of Coyote Creek.

Wildlife. The structural diversity of the mixed riparian woodland and forest habitat in the Project Area supports a high diversity of animal species. Riparian forests provide habitat for relatively high densities of native nesting songbirds, such as the song sparrow, Pacific-slope flycatcher (*Empidonax difficilis*), black-headed grosbeak (*Pheucticus melanocephalus*), warbling vireo (*Vireo gilvus*), chestnut-backed chickadee (*Poecile rufescens*), oak titmouse (*Baeolophus inornatus*), bushtit (*Psaltriparus minimus*), house wren (*Troglodytes aedon*), American robin (*Turdus migratorius*), and many others. During spring and fall migration, high densities of migrant songbirds forage in these habitats. Oak and sycamore trees also support cavity-nesting bird species, such as woodpeckers and American kestrels (*Falco sparverius*). Leaf litter, downed tree branches, and fallen logs provide cover for the arboreal salamander (*Aneides lugubris*), slender salamander (*Batrachoseps attenuatus*), and several lizards may also occur here, including the western fence lizard (*Sceloporus occidentalis*), western skink (*Eumeces skiltonianus*), and southern alligator lizard (*Elgaria multicarinata*). Small mammals, such as the ornate shrew (*Sorex ornatus*), California vole (*Microtus californicus*), and Audubon's cottontail (*Sylvilagus audubonii*), use these riparian habitats as well. Medium-sized mammals, such as the raccoon, striped skunk (*Mephitis mephitis*), and bobcat (*Lynx rufus*), also occur in this land cover type.

Willow Riparian Forest and Scrub

Habitat Conditions/Vegetation. No willow riparian forest and scrub is present within the Seismic Retrofit Area or Coyote Percolation Dam CM Area. At the Ogier Ponds CM Area, this land cover type occurs in a number of locations. It is present along the segments of Coyote Creek that flow into and through the pond complex, around the perimeters of some of the pond/reservoir land cover types, and in a portion of the historical Coyote Creek channel downstream from Ogier Avenue. This land cover type is dominated by arroyo willow, red willow, and Fremont cottonwood, often in very dense stands. Willow riparian forest and scrub is also present along several segments of Coyote Creek between the Seismic Retrofit and Coyote Percolation Dam CM Areas. A limited area of willow riparian forest and scrub will have been created in the North Channel Reach by the FOCP just prior to ADSRP initiation.

Wildlife. The animals associated with willow riparian forest and scrub are largely the same as those described above for mixed riparian woodland and forest.

California Annual Grassland

Habitat Conditions/Vegetation. California annual grassland is an herbaceous plant community dominated by nonnative annual grasses. Within the Seismic Retrofit Area, this land cover type is found on the downstream dam face, in areas within the BHBA and along access roads to that borrow area, along the edge of the reservoir rim (just above the high-water line), and within the Live Oak Picnic Area. This land cover type also dominates most of the upland portions of the Ogier Ponds CM Area, as well as most upland areas along Coyote Creek between the Seismic Retrofit and Coyote Percolation Dam CM Areas. Dominant species include nonnative grasses such wild oats (*Avena fatua*), bromes (*Bromus* spp.), and Italian rye grass (*Festuca perennis*). Common nonnative and native forbs include clovers (*Trifolium* spp.), filarees (*Erodium* spp.), Jersey cudweed (*Pseudognaphalium luteoalbum*), lupines (*Lupinus* spp.), yarrow (*Achillea millefolium*), and California poppy (*Eschscholzia californica*). Several invasive weeds are also common, including yellow star-thistle (*Centaurea solstitialis*), bull thistle (*Cirsium vulgare*), and milk thistle (*Silybum marianum*). In addition, several small patches of native bunchgrass habitat are present around Anderson Dam (such as in and just north of the BHBA) within areas mapped as California annual grassland or in small openings within other habitat types. Purple needlegrass (*Stipa pulchra*) is the dominant species in these native grasslands.

Wildlife. Small mammals such as the California ground squirrel (*Otospermophilus beecheyi*), valley pocket gopher (*Thomomys bottae*), and deer mouse (*Peromyscus maniculatus*) are common residents of annual grasslands in the Project Area. Black-tailed deer (*Odocoileus hemionus*) are common browsers, and other large mammals, especially crepuscular and nocturnal mammals such as the coyote (*Canis latrans*) and bobcats, forage in grasslands as well. Vegetation within much of the grassland in the Project Area is too sparse to support ground-nesting grassland birds, but areas with higher densities of grassland vegetation support common grassland-nesting bird species, such as the western meadowlark (*Sturnella neglecta*). Additional bird species that nest in adjacent habitats frequently forage in grasslands. These include lark sparrow (*Chondestes grammacus*), western bluebird (*Sialia mexicana*), barn swallow (*Hirundo rustica*), violet-green swallow (*Tachycineta thalassina*), red-tailed hawk (*Buteo jamaicensis*), and white-tailed kite (*Elanus leucurus*). Grassland provides abundant refugia for reptiles, with numerous large rocks to provide crevices for refuge and hunting. Reptile species occurring in the annual grassland in the Project Area include the western fence lizard, gopher snake (*Pituophis catenifer*), northern Pacific rattlesnake (*Crotalus oreganus*), and western terrestrial garter snake (*Thamnophis elegans*).

Mixed Serpentine Chaparral

Habitat Conditions/Vegetation. Mixed serpentine chaparral occurs in the Seismic Retrofit Area on dry slopes underlain by serpentine soils. The majority of mixed serpentine chaparral is present on the northern side of the Anderson Dam spillway (including both the concrete-lined and unlined portions), where extensive stands of this land cover type covering the ridge to the north barely extend into the Project Area. Smaller areas of mixed serpentine chaparral are present within the Project Area just northeast of the spillway and northeast of the boat ramp at Anderson Dam; in both areas, Project activities will extend into the chaparral above the reservoir rim, into mixed serpentine chaparral. Coyote ceanothus forms dense stands and dominates this land cover type. Other common shrubs include California sagebrush (*Artemisia californica*), toyon (*Heteromeles arbutifolia*), coyote brush, and bigberry manzanita (*Arctostaphylos glauca*). This habitat also includes several small serpentine rock outcrops at the base of Silica Carbonate Hill. Just outside the Project footprint, Santa Clara Valley dudleya occur on these outcrops, though none are present within the construction footprint itself.

Wildlife. The mixed serpentine chaparral provides nesting habitat for birds, such as the California scrub-jay (*Aphelocoma californica*), California towhee (*Melozone crissalis*), spotted towhee (*Pipilo maculatus*), wrentit (*Chamaea fasciata*), California thrasher (*Toxostoma redivivum*), lesser goldfinch (*Spinus psaltria*), and Anna's hummingbird (*Calypte anna*). Mammal species that use such scrub habitat include the coyote, California mouse (*Peromyscus californicus*), and brush rabbit (*Sylvilagus bachmani*). Reptiles that occur here include the gopher snake, northern Pacific rattlesnake, southern alligator lizard, and western fence lizard.

Northern Coastal Scrub/Diablan Sage Scrub

Habitat Conditions/Vegetation. The northern coastal scrub/Diablan sage scrub land cover type occurs on dry, exposed slopes with shallow soils within the Seismic Retrofit Area. This land cover type includes several different shrub communities that intergrade on the site. Areas of northern coastal scrub/Diablan sage scrub in the BHBA are dominated by coyote brush and support little plant diversity. A large contiguous patch of scrub habitat on the right (north) abutment of Anderson Dam and patches along the southern edge of the unlined portion of the Anderson Dam spillway and in the former Chert Hill quarry area support a diverse assemblage of native shrubs, including California sagebrush, black sage (*Salvia mellifera*), and yerba santa (*Eriodictyon californicum*). California buckwheat (*Eriogonum fasciculatum*), sticky monkey flower (*Diplacus aurantiacus*), Coyote ceanothus, and bigberry manzanita also occur in this land cover type. In areas with dense shrub cover, there is very little herbaceous community; however, occasional openings support both native and nonnative grasses and forbs.

Wildlife. Animals using the northern coastal scrub/Diablan sage scrub land cover type are similar to those described above for mixed serpentine chaparral.

Coast Live Oak Forest and Woodland

Habitat Conditions/Vegetation. In the Seismic Retrofit Area, coast live oak forest and woodland generally occur on mesic (moderately moist) slopes and in lowland areas with relatively deep, fertile soil. The majority of this land cover type occurs on flat terrain along Coyote Creek in the Live Oak Picnic Area, directly north of Cochrane Road. Smaller patches are present on the northeast side of the BHBA and along its associated access road.

At the Ogier Ponds CM Area, coast live oak forest and woodland is present along the southwestern terrace above the historical Coyote Creek channel on either side of Ogier Avenue and in one small patch southeast of Pond 4. Coast live oak is the dominant tree species. The majority of areas mapped as this land cover type are woodlands with open canopies; however, several relatively small but dense patches support overlapping canopies and could be classified as forest. This land cover type also includes occasional California bay (*Umbellularia californica*) and California sycamore trees. Common woody understory species include toyon and California blackberry. The herbaceous community is similar to that of the California annual grassland community but with a greater component of native forbs and grasses.

Wildlife. The coast live oak forest and woodland land cover type provides good cover, nesting/roosting opportunities, and a diversity of foraging opportunities for wildlife species. Oaks provide nesting and foraging opportunities for cavity-nesting birds such as the western bluebird, white-breasted nuthatch (*Sitta carolinensis*), Nuttall's woodpecker (*Picoides nuttallii*), and oak titmouse. Raptors such as the Cooper's hawk (*Accipiter cooperii*) and American kestrel may nest in large oaks. Acorns provide food for a number of wildlife species, including the acorn woodpecker (*Melanerpes formicivorus*), California quail (*Callipepla californica*), and California scrub-jay. San Francisco dusky-footed woodrats (*Neotoma fuscipes annectens*) and other small rodents, especially those associated with adjacent scrub, grassland, and riparian habitats, occur in oak woodlands on the site. Coast live oak woodlands provide cover for bobcats and coyotes that may occasionally wander through the site. Several species of amphibians, such as the arboreal salamander, can be found in oak woodlands, especially where moisture is retained under fallen wood and in crevices in oaks. Reptiles that occur here include the ringneck snake (*Diadophis punctatus*) and western skink.

Foothill Pine-Oak Woodland

Habitat Conditions/Vegetation. Foothill pine-oak woodland generally occurs in drier areas with shallow soils and often intergrades with scrub and chaparral habitats. In the Seismic Retrofit Area, this land cover type occurs throughout much of the rocky BHBA, on portions of the right (north) abutment of Anderson Dam, and on slopes north of the unlined portion of the spillway and in the Chert Hill area. The dominant tree species is foothill pine (*Pinus sabiniana*). In disturbed areas, the understory is often dominated by nonnative, invasive species including pampas grass (*Cortaderia jubata*). In less disturbed areas, the understory contains a higher proportion of native trees and shrubs, including coast live oak, coyote brush, and toyon. The herbaceous layer is generally similar to that in the California annual grassland habitat but is sparse in some areas due to a buildup of pine needles and thatch.

Wildlife. Adjacent chaparral, coastal scrub, and annual grassland communities contribute to the species found in the small patches of foothill pine-oak woodland. Common amphibians and reptiles such as the slender salamander, western fence lizard, gopher snake, southern alligator lizard, racer (*Coluber constrictor*), and common kingsnake (*Lampropeltis getula*) make use of downed tree branches under pine and oak trees in this habitat. Bird species commonly found in mixed pine-oak woodlands include the western bluebird, acorn woodpecker, northern flicker (*Colaptes auratus*), white-breasted nuthatch, and other cavity-nesting species. Raptors, such as red-tailed hawks, as well as predatory mammals, such as coyotes, forage on ground squirrels and other small mammals that are often present in mixed woodland habitats.

Grain, Row-Crop, Hay and Pasture, Disked/Short-Term Fallowed

Habitat Conditions/Vegetation. The grain, row-crop, hay and pasture, disked/short-term fallowed land cover type occurs in the Project Area only at the Ogier Ponds CM Area. There, this land cover type is represented by an agricultural field on the northwest side of the Monterey Road/Barnhart Avenue intersection. Based on a review of aerial photos, this field is disked frequently and has been mostly bare in recent years, though it has apparently been planted in hay in some years. Weedy plant species, such as those occurring in California annual grassland described above, likely occur in this field when it is fallow.

Wildlife. Wildlife use of the grain, row-crop, hay and pasture, disked/short-term fallowed land cover type is limited due to the absence of vegetation much of the time and the structural simplicity of the vegetation when hay is planted. Western meadowlarks, American pipits (*Anthus rubescens*), and red-winged blackbirds forage in this field, but it is unlikely that any birds nest there. A variety of mammals may move through, or occasionally forage in, this field, but none den there.

Urban-Suburban

Habitat Conditions/Vegetation. The urban-suburban land cover type includes developed/artificial habitats such as access roads, parking lots, structures (including the dam spillway), park facilities associated with Anderson Lake County Park, and landscaped areas. This land cover type also includes areas with a very low cover of ruderal species, similar to those occurring within the California annual grassland plant community, growing on the rocky soils east of the dam crest. Several earthen or concrete-lined swales occur directly adjacent to the existing roads. Urban-suburban areas are also present along roads at the Ogier Ponds CM Area and hardscaped and graveled areas at the Coyote Percolation Dam CM Area. Landscaped areas support a variety of nonnative and native species, including Peruvian pepper tree (*Schinus molle*), rosemary (*Rosmarinus officinalis*), and planted coast live oaks.

Wildlife. Developed habitats in the urban-suburban land cover type are used for foraging by a variety of animals associated with adjacent, less developed land cover types. Some species, such as the black phoebe (*Sayornis nigricans*), house finch (*Haemorhous mexicanus*), barn swallow, and cliff swallow (*Petrochelidon pyrrhonota*), nest on artificial structures, such as those at Anderson Dam, and the northern rough-winged swallow (*Stelgidopteryx serripennis*) and violet-green swallow nest in weep holes in the concrete spillway of Anderson Dam.

Central California Sycamore Alluvial Woodland

Habitat Conditions/Vegetation. The central California sycamore alluvial woodland land cover type is absent from the Seismic Retrofit, Ogier Ponds CM, and Coyote Percolation Dam CM Areas, and no Project construction activities are proposed or expected to occur in sycamore alluvial woodland. However, this land cover type is described here, because it is present in two areas along Coyote Creek between the Seismic Retrofit Area and the Coyote Percolation Dam CM Area. Sycamore alluvial woodland is present on the northeast side of Coyote Creek just downstream from US 101 (upstream from the Ogier Ponds) and adjacent to the Coyote Creek Golf Course. Sycamore alluvial woodland occurs in broad floodplains with deep alluvial material and is dominated by western sycamores, with lesser numbers of species, such as willows and coast live oak. The sycamores are widely spaced, allowing ample light to reach the ground, so that ground cover is similar in most areas to California annual grassland.

Wildlife. Sycamore alluvial woodland supports a variety of wildlife species, including many of those associated with mixed riparian forest and woodland, willow riparian forest and scrub, and California annual grassland. Mature sycamores often have cavities that provide dens for raccoons, roost sites for bats, and nest sites for birds, such as the northern flicker, western bluebird, acorn woodpecker, tree swallow (*Tachycineta bicolor*), wood duck (*Aix sponsa*), and common merganser (*Mergus merganser*).

Habitat Conditions and Characteristic Species in the Expanded Study Area

In addition to affecting terrestrial biological resources in the Project Area, the Project would also result in impacts on biological resources in additional portions of the study area that are outside the Seismic Retrofit Area and Conservation Measures Project Areas, and are thus not described above. These additional portions of the study area, called the expanded study area, are described below. The limits of the expanded study area cannot be defined precisely due to uncertainty regarding the extent to which indirect effects (such as effects of nitrogen emissions and deposition) may occur, but **Figure 3.5-1** constitutes a good base reference for purposes of identifying the additional portions of the study area described in the following bullets:

- Areas immediately adjacent to the Seismic Retrofit Area and Conservation Measures Project Area, where Project activities may disturb special-status animals through noise or construction activities, or special-status plants through dust mobilized by construction activities. These adjacent areas generally consist of the same land cover types that are within the portions of the Project Area to which they are adjacent and are thus dominated by the same plant and animal species described above for those land cover types. At the Seismic Retrofit Area, adjacent habitat areas will have been affected to varying degrees by noise, construction activity, dust mobilization, and other impacts from FOCP activities. However, in contrast to the areas included in the “Disturbed by FOCP” category in **Table 3.5-1**, these adjacent areas will still retain their pre-FOCP land cover types.
- Portions of lower Coyote Creek and Upper Penitencia Creek that would serve as Central California coast steelhead (*Oncorhynchus mykiss*) relocation sites if steelhead need to be relocated from the CWMZ during Project construction. Steelhead may be relocated to Coyote Creek near its confluence with Upper Penitencia Creek and/or the reach of Upper Penitencia Creek in Alum Rock Park. Land cover types in both areas consist of perennial stream, mixed riparian woodland forest, and urban-suburban, and characteristic plant and animal species are as described above for those three land cover types.
- Coyote Creek from Anderson Dam downstream to south San Francisco Bay, approximately 32 stream miles to the uppermost tidal areas and 40 stream miles to the open Bay, that could be affected by changes in flow rates and sediment mobilization during Project construction; the lower limits of this impact area, at the mouth of Coyote Slough, were established by modeling of sediment mobilization (URS ~~AECOM~~ 2021). From Anderson Dam downstream to the upper limits of tidal influence, land cover types include primarily perennial stream, mixed riparian woodland and forest, willow riparian forest and scrub, coastal and valley freshwater marsh, and urban-suburban. Limited areas of central California sycamore alluvial woodland, which is dominated by California sycamore, are also present (e.g., just downstream from US 101 between Anderson Dam and the Ogier Ponds, and just downstream from the Ogier Ponds). In tidally influenced

areas, land cover types include tidal brackish marsh dominated by California bulrush, alkali bulrush (*Bolboschoenus maritimus* subsp. *paludosus*), cattails, and perennial pepperweed (*Lepidium latifolium*), and tidal salt marsh dominated by Pacific cordgrass (*Spartina foliosa*), pickleweed (*Sarcocornia pacifica*), and marsh gumplant (*Grindelia stricta*). These tidal marshes support a suite of specialized animals, including the California Ridgway's rail (*Rallus obsoletus obsoletus*), California black rail (*Laterallus jamaicensis coturniculus*), Alameda song sparrow (*Melospiza melodia pusillula*), San Francisco common yellowthroat (*Geothlypis trichas sinuosa*), marsh wren (*Cistothorus palustris*), and salt marsh harvest mouse. Tidal areas at elevations too low to support emergent vegetation consist of subtidal areas that are inundated even at the lowest tides and intertidal mudflats that are exposed during low tide. A variety of waterbirds forage in such habitats, including ducks such as the canvasback (*Aythya valisineria*), green-winged teal (*Anas crecca*), and lesser scaup (*Aythya affinis*) and shorebirds such as the long-billed curlew (*Numenius americanus*), marbled godwit (*Limosa fedoa*), western sandpiper (*Calidris mauri*), willet (*Tringa semipalmata*), and short-billed dowitcher (*Limnodromus griseus*).

- Areas along Coyote Creek and in North Coyote Valley supporting wetland (coastal and valley freshwater marsh and seasonal wetland), aquatic (pond and perennial stream), or riparian (mixed riparian woodland, and forest and willow riparian forest and scrub) habitats dependent on groundwater, which could be subject to reduced water availability if Coyote Creek flows decrease during Project construction. The characteristic plant and animal communities present in these areas are as described for these land cover types above. However, seasonal wetlands are much more extensive in North Coyote Valley than they are in the Project Area. In particular, Laguna Seca is a large seasonal wetland in North Coyote Valley (see **Figure 3.5-1**). During wet years, Laguna Seca becomes a large, shallow lake that provides foraging habitat for a variety of waterfowl in winter. As Laguna Seca draws down in spring, it becomes vegetated with a variety of seasonal wetland plants, and after particularly high-rainfall years, it may hold water long enough to support nesting by ducks and by shorebirds such as the black-necked stilt (*Himantopus mexicanus*).
- Serpentine communities (e.g., serpentine bunchgrass grassland and mixed serpentine chaparral), such as those on Coyote Ridge, that would be adversely affected by nitrogen emissions from equipment and vehicles during Project construction, and thus by the Project's contribution to cumulative effects of nitrogen deposition. The serpentine bunchgrass grasslands subject to such effects include much more extensive, higher-quality grassland, such as that dominating Coyote Ridge to the north of Anderson Dam, than is present in the Project Area. Serpentine bunchgrass grassland on Coyote Ridge supports native plant communities dominated by purple needlegrass and a variety of forbs, including rare plants such as Santa Clara Valley dudleya, Metcalf Canyon jewel-flower, and most beautiful jewel-flower (*Streptanthus glandulosus* ssp. *glandulosus*). Several invertebrate species, including the federally threatened Bay checkerspot butterfly, depend on serpentine bunchgrass grasslands because their host food plants are found primarily in these habitats.

Given the vast extent of this expanded study area, the uncertainty regarding the precise locations of impacts to this area, and the fact that impacts within the additional portions of the study area would not change habitat/land cover types, the habitat/land cover types within the expanded study area have not been mapped or quantified as those within the Project Area have.

3.5.1.2 Aquatic Resources and Other Sensitive Habitats

Waters of the U.S./Waters of the State[1]

As described in the Regulatory Setting section below, impacts to wetlands and other waters of the U.S. and waters of the State are regulated under sections 404 and 401 of the federal Clean Water Act (CWA) and under the Porter-Cologne Act. Some features within the Project Area are expected to be considered by the USACE to be waters of the U.S. and by the SWRCB to be waters of the State. These features include the reservoir, pond, coastal and valley freshwater marsh, and seasonal wetland land cover types depicted on **Figure 3.5-2** through **Figure 3.5-7**, as well as the Anderson Dam spillway and perennial and intermittent streams. These features were identified during field delineations to identify regulated habitats (Valley Water 2024b ~~2022c~~). Most of the regulated waters are unvegetated "other waters," including Anderson Reservoir, Coyote Creek, pond, and reservoir land cover types at the Ogier Ponds and Coyote Percolation Dam, and intermittent streams. In addition, vegetated wetlands, including coastal and valley freshwater marsh and seasonal wetland, are also present. The precise extent to which these features are jurisdictional waters of the U.S./State will be verified later pursuant to jurisdictional delineations submitted to USACE and the SWRCB.

Potentially jurisdictional wetlands and other waters present within the Seismic Retrofit Area, Ogier Ponds CM Area, ~~and~~ Coyote Percolation Dam CM Area, and North Channel Reach and Live Oak Restoration Reach Maintenance areas under baseline conditions are summarized in **Table 3.5-3**. All features that possess the characteristics of waters of the U.S. were determined by Valley Water (2024b ~~2022c~~) to be waters of the U.S. (e.g., none are considered to be nonjurisdictional, for example, due to isolation from navigable waters). Whereas USACE jurisdiction over waters of the U.S. extends upslope only as far as the ordinary high-water mark (OHWM) along streams and other waterbodies, in general the SWRCB may claim jurisdiction over riparian habitats upslope from the OHWM as waters of the State, to the top of bank or the outer edge of the canopy of riparian habitat rooted below top of bank, whichever is greater. Therefore, the presumed extent of waters of the State in the Project Area is greater than the extent of waters of the U.S., as indicated in **Table 3.5-3**.

In addition, waters of the U.S. and waters of the State are present within the expanded study area, such as along Upper Penitencia Creek, in Coyote Valley, and along Coyote Creek between the Project Area and San Francisco Bay. These waters have not been mapped or quantified, as fish relocation to Upper Penitencia Creek would not result in the loss of any waters of the U.S. and State, and no Project activities resulting in temporary or permanent loss of waters would be performed in regulated habitats in Coyote Valley or along lower Coyote Creek.

[1] Acreage of Waters of the U.S. in the environmental setting and proposed for creation were estimated using regulatory definitions that existed at the time the ~~this~~ Draft EIR was being prepared. Subsequently, the Supreme Court case Sackett v. EPA (2023), 143 S. Ct. 132)2 limited the types of wetlands that should be considered Waters of the U.S.~~WOTUS~~. This change in definition would likely lower the acreages of wetlands considered Waters of the U.S. ~~WOTUS~~that are presented in this ~~the~~ Final ~~Draft~~ EIR and would be implemented through revised regulatory definitions being drafted at the time the Draft EIR was released.

Beds and Banks Regulated under the Fish and Game Code Section 1600 et seq.

As described in the Regulatory Setting section below, the CDFW regulates diversions or activities that alter the bed and banks of rivers, lakes, and streams in the state. In the Project Area, features whose alteration would be regulated include the reservoir, perennial stream, and intermittent stream land cover types; the Anderson Dam spillway; ponds that are in-line with streams, such as the pond just below the lined portion of the spillway; and coastal and valley freshwater marsh, seasonal wetland, and riparian habitats associated with those features. In general, CDFW jurisdiction over such features extends upslope to the top of bank or the outer edge of the riparian canopy, whichever is greater.

Table 3.5-3. Jurisdictional Aquatic Resources in the Seismic Retrofit, Ogier Ponds CM, Coyote Percolation Dam CM, North Channel Reach ~~Extension~~, and Live Oak Restoration Reach Areas[1]

Project Component	Waters of the U.S.		Waters of the State		CDFW-Regulated Habitats

~~Source: Valley Water 2022c~~

~~Notes:~~

~~Locations and extents of Conservation Measures such as sediment augmentation have not yet been determined, so the acreage and linear footage of impacts from those activities are not yet known. It is expected that impacts of those activities on jurisdictional aquatic resources will be much lower than for the three Project components listed in this table.~~

[1] Impact totals include jurisdictional waters that ~~Totals for the Seismic Retrofit Area do not include approximately 1.98 acres and 1,674 linear feet of perennial stream that~~ will have been impacted by the FOCP prior to the start of Seismic Retrofit construction but that will still be jurisdictional.

~~[2] Totals for the Coyote Percolation Dam CM Area do not include approximately 65 linear feet of perennial stream that will have been impacted by the FOCP prior to the start of Coyote Percolation Dam CM construction.~~

~~[3] Acreages and linear footages for the Live Oak Restoration Reach in this table do not include portions of that Conservation Measure that overlap the North Channel Extension (0.002 acres and 17 linear feet of intermittent stream, 0.02 acres and 72 linear feet of perennial stream, and 0.2 acres of mixed riparian woodland and forest) or Seismic Retrofit Area (0.68 acres and 990 linear feet of perennial stream, 0.003 acres of coastal and valley freshwater marsh, and 2.87 acres of mixed riparian woodland and forest).~~

Key: CDFW = California Department of Fish and Wildlife; CM = Conservation Measures

Features that are expected to be regulated by CDFW under Section 1602 of the Fish and Game Code within the Seismic Retrofit Area, Ogier Ponds CM Area, and Coyote Percolation Dam CM Area are summarized in **Table 3.5-3**. These features were identified during field delineations to identify regulated habitats (Valley Water 2024b ~~2022c~~). In addition, CDFW-regulated habitats are present within the expanded study area, such as along Upper Penitencia Creek, in Coyote Valley, and along Coyote Creek between the Project Area and San Francisco Bay. These habitats have not been mapped or quantified, as fish relocation to Upper Penitencia Creek will not result in the loss of any such habitats, and no Project activities will be performed in regulated habitats in Coyote Valley or along lower Coyote Creek.

Other Sensitive Habitats

CDFW Natural Communities of Special Concern. CDFW natural communities of special concern are those that are of limited distribution statewide or within a county or region. These communities may or may not contain special-status species or their habitat. Most types of wetlands and riparian communities are considered special-status natural communities because of their limited distribution in California and their ecological importance. Additional CDFW natural communities of special concern mapped in the Project Area include serpentine bunchgrass and mixed serpentine chaparral (Holland 1986, Sawyer et al. 2009).

As described previously, serpentine bunchgrass grassland (present on Coyote Ridge and in other areas near the Project Area) and mixed serpentine chaparral generally support native plant communities including rare plants, such as the federally listed Coyote ceanothus, Santa Clara Valley dudleya and Metcalf Canyon jewel-flower, and the CRPR 1B most beautiful jewel-flower. Several invertebrate species, including the federally threatened Bay checkerspot butterfly, depend on serpentine bunchgrass grasslands because their host food plants are found primarily in these habitats. Likewise, serpentine outcrops/barrens, serpentine chaparral, and serpentine seeps are considered sensitive communities (ICF 2012) because of their importance to serpentine-endemic plants and invertebrates, and their limited regional distribution. The locations of, and habitat conditions within, the mixed serpentine chaparral land cover type in the Project Area is described above, and their locations are shown on **Figure 3.5-3**. Several very small patches of native-dominated bunchgrass also occur outside of serpentine soils, though they are too small to be mapped separately. Northern coastal salt marsh is also considered a sensitive community by CDFW. Although this habitat is absent from the Seismic Retrofit Area and Conservation Measures Project Area, it is present in tidal habitats along lower Coyote Creek/Coyote Slough that could be affected by high flows and sediment mobilized during Project construction.

Oak Woodlands. Oak woodlands are considered one of California's most productive and important natural communities. They support a rich plant and wildlife community; at least 60 of California's 169 terrestrial mammal species and approximately 60 species of birds are associated with oak woodlands (County 2005). In addition, oak trees play an important role in helping to maintain water quality in streams and rivers by reducing erosion, yet more than a million acres of oak savanna and oak woodlands in California are estimated to have been lost since 1945 (County 2005).

Areas in the Project Area mapped as coast live oak forest and woodland, and foothill pine-oak woodland, meet the State-regulatory definition of oak woodland because of their size, tree density, and connection to adjacent oak woodland. Areas mapped as mixed riparian woodland

and forest also meet the definition of oak woodland where coast live oak is a dominant species. No blue oak (*Quercus douglasii*) or valley oak (*Quercus lobata*) woodlands as defined or mapped by the VHP are present in the Project Area or elsewhere in the study area.

3.5.1.3 Invasive Species and Pathogens

Invasive Species

For over two centuries, humans have brought nonnative plants and animals into the Project vicinity, either accidentally (e.g., as stowaways on recreational equipment) or intentionally (e.g., released pets), and many of these species have now been introduced into the wild. Such species that cause harm and, once established, spread quickly from their point of introduction are often called "invasive" species.

Invasive species can threaten the diversity and abundance of native species through predation, competition for resources, transmission of disease, parasitism, and physical or chemical alteration of the habitat. Their effects on natural communities also may lead to direct effects on human activities, such as clogging waterways and water delivery systems, weakening flood protection structures, damaging crops, and diminishing sport fish populations (CDFW 2018).

A number of plant species that are considered invasive (California Invasive Plant Council [Cal-IPC] 2022) are present in portions of the Project Area. The more common and widespread of these species include yellow star-thistle, bull thistle, milk thistle, oats (*Avena* spp.), ripgut brome (*Bromus diandrus*), eucalyptus (*Eucalyptus* spp.), Russian thistle, poison hemlock (*Conium maculatum*), fennel (*Foeniculum vulgare*), pampas grass, and black mustard (*Brassica nigra*). These plants easily colonize disturbed areas or substrate that is not otherwise dominated by native plants, such as the bed and banks of Anderson Reservoir as it has been drawn down.

In addition, several invasive animals are present in the Project Area. The American bullfrog has been accidentally and intentionally introduced (e.g., for food in the 1920s by commercial frog farmers) throughout the world and is now established throughout most of the western United States. The species' large size, mobility, generalized eating habits (their prey includes native amphibians such as California red-legged frog, foothill yellow-legged frog, and California tiger salamander as well as other aquatic and riparian vertebrates [Graber 1996]), and aggressive behavior have made bullfrogs extremely successful invaders and a threat to biodiversity. Nonnative turtles, particularly the red-eared slider, compete with the native <u>north</u>western pond turtle for high-quality basking sites. Nonnative species, such as feral house cats (*Felis felis*) and red fox (*Vulpes vulpes*), are known to occur in the Project Area and are predators of native birds and small mammals.

Feral pigs (*Sus scrota*; also called wild boars), which are present around Anderson Reservoir, the Ogier Ponds, and elsewhere along Coyote Creek outside of the most heavily urbanized areas, can damage natural habitats through herbivory, rooting, wallowing, and soil compaction. In California, feral pigs occur in a wide variety of habitats, including oak woodlands, mixed forests, grassy savannas, and other habitats. They move widely within their home range according to resource availability and weather. On average, boars have territorial sizes of 1.1 to 3.9 square kilometers (about 0.4 to 1.5 square miles). Female sounders (groups of pigs) tend to occupy a smaller region and keep to covered areas within a home range to protect themselves and their young. Feral pigs reproduce prolifically; females may become sexually mature at less than 1 year of age and may produce up to four litters per year, including up to 18 piglets per litter (Rust 2022).

Feral pigs require a nearby water source and dense vegetation for shelter to protect and conceal themselves from predators. They commonly use nearby woody vegetation for basic life functions. In warmer weather they are more inactive during the day, stay in shade, wallow in water sources to keep cool, and forage in the evening and night. If feral pigs actively feed during the day, they tend to avoid open areas that would make them more vulnerable to predation. Feral pigs are opportunistic omnivores. They are generalists and will readily eat whatever is available. They eat primarily plant material such as roots, bulbs, seeds, green plants, agriculture crops, fruit, and acorns, but they will also consume bird and reptile eggs, small rodents, amphibians, insects, and worms. Feral pigs will also eat human food. Land use authorities with feral pig experience consistently report a general opinion that feral pigs follow food sources. During dry years and in winter, feral pigs may expand their home ranges in search of high-quality feeding areas (University of California Agriculture and Natural Resources 2023).

Numbers of feral pigs in California are likely in the hundreds of thousands (Rust 2022), and feral pigs are present in the foothills and valley floor surrounding Anderson Reservoir and along Coyote Creek on the valley floor. County Parks has been managing pigs since 1994 (https://parks.sccgov.org/feral-pigs) and reports the presence of feral pigs to the south and west of Anderson Dam, in nearby County Park facilities, including Rosendin Park, Coyote Creek Parkway, and Coyote Lake Harvey Bear Ranch Park. California State Parks has noted that Henry Coe State Park, located to the east of Anderson Reservoir, is believed to support hundreds if not thousands of feral pigs. The Santa Clara Valley Open Space Authority has observed feral pigs on its Coyote Ridge Preserve, north of Anderson Dam. Valley Water staff have confirmed feral pigs at Valley Water's Coyote Ridge Preserve and is also aware of feral pig management at Coyote Creek Golf Course and Kirby Canyon Landfill, all north of Anderson Dam.

Numerous news stories and social media accounts (including NextDoor) document the presence of feral pigs throughout the South Valley region. Feral pigs have a documented history of moving into or through neighborhoods adjacent to Anderson Reservoir. As evidenced by a growing number of encounters within suburban and valley habitats throughout southern Santa Clara County, their populations can be assumed to be growing, and range expansion is possible.

There is no clear evidence that the drawdown of Anderson Reservoir as mandated by DSOD and FERC has resulted in changes to feral pig movement and distribution around Anderson Reservoir. This species' populations have been increasing throughout the region over the past several decades, and they are occurring in more areas, more regularly, and in greater abundance throughout the South Bay as a result, irrespective of the drawdown of Anderson Reservoir. As a result, feral pigs have caused damage to private property and residential neighborhoods throughout the region, including neighborhoods in Almaden Valley, Coyote Valley, Evergreen, Guadalupe Mines, Metcalf, Santa Teresa, and Silver Creek districts of San Jose, in addition to neighborhoods near Anderson Reservoir. Requests from residents and businesses for relief from feral pig damage has recently spurred the City of San José to take action and explore possible ordinance changes to facilitate the management of pigs within city boundaries.

Pathogens

Plant and animal pathogens, which can be spread by human activities, can also adversely affect native species and communities. *Phytophthora* is a taxonomic group of microscopic oomycetes (also known as water molds). More than 170 *Phytophthora* species have been described, and almost all are known to be pathogenic to plants. Plant diseases caused by *Phytophthora* include root rots, stem cankers, and fruit and leaf blights. *Phytophthora* is transmitted through the movement of contaminated soil and water, and some species are known to be airborne. Movement of contaminated soil, water, and plant material are primary pathways for spreading infection. Areas with woody vegetation and susceptible host plants are at greatest risk of being infested. Once introduced into native habitats, *Phytophthora* persists in soil and infected host roots and is very difficult to impossible to eradicate (Swiecki and Bernhardt 2017 ~~2014~~). Spread of contamination could result in long-term impairment of the health of native vegetation, resulting in declines in abundance of sensitive plant species and communities (Swiecki 2020).

Phytophthora has been detected at Anderson Dam and Reservoir on the western dam abutment near an historical set of restoration plantings, and adjacent to the boat launch in association with high-water flooding (Phytosphere Research 2018). It has also been detected along Lakeview Trail east of the boat launch, on the reservoir's south shore northeast of the boat launch, and along the reservoir's north shore east of the spillway (Phytosphere Research 2018). *Phytophthora* has not been detected at other sampling locations near the Lakeview Trail and north of the spillway on the south-facing slope. *Phytophthora* is known to occur throughout much of the San Francisco Bay Area and California. Because *Phytophthora* can disperse in water and water runoff, and because it has been detected at Anderson Dam and Reservoir, it is assumed that all Project sites located downstream of Anderson Dam and Reservoir are potentially contaminated.

Other pathogens can adversely affect animals. Ranaviruses can cause impaired health or mortality of amphibians, turtles, and fish. These viruses are transmitted through direct contact between infected and uninfected animals, contaminated water, or predation (e.g., ingestion of infected animals). Chytrid fungus is a water-borne fungus that can impair the health of amphibians. There are approximately 1,000 chytrid species, and *Batrachochytrium dendrobatidis* can infect the skin of amphibians (Longcore et al. 1999). Infected individuals may develop chytridiomycosis, a thickening of the skin that inhibits amphibians' ability to absorb water and electrolytes, eventually causing death (Voyles et al. 2009). Chytridiomycosis outbreaks have been linked to substantial declines in some amphibian populations (Berger et al. 1998, Fisher et al. 2009). Chytrid fungus may be spread by the dispersal of infection by translocation of zoospores by other animals or humans (including equipment and machinery) among waterbodies. Chytrid has been recorded in the upper watershed of Upper Penitencia Creek (Padgett-Flohr and Hopkins 2010) and was detected there by Valley Water in 2021, during monitoring associated with FOCP fish relocation efforts (Valley Water 2022b ~~2022a~~).

Shell disease can affect the health of northwestern pond turtles. Caused by fungal or bacterial infections, shell disease can result in lesions or irregularities in turtles' shells. This disease is known best in captive or domestic turtles, but there is concern that it could affect wild turtles, such as northwestern pond turtles (Washington Department of Fish and Wildlife 2016).

3.5.1.4 Special-Status Plant and Animal Species

CEQA requires an assessment of the effects of a project on species that are "threatened, rare, or endangered;" such species are typically described as "special-status species." For planning purposes and for assessment of impacts of the Project, special-status species have been defined as described below. Impacts on these species are reviewed in accordance with CEQA requirements, and some species are also regulated by federal and State laws and ordinances described in the Regulatory Setting section.

Special-Status Plants

Special-status plants that may occur in the study area, including not only the Project Area but also other areas that could be impacted by Project activities (i.e., the expanded study area), are discussed in **Table 3.5-4**. For purposes of this analysis, special-status plants are plant species that meet at least one of the following criteria:

- listed under ESA as threatened, endangered, proposed for listing as threatened, proposed for listing as endangered, or a candidate species for listing
- listed under CESA as threatened, endangered, rare, or a candidate species for listing
- included in the CNPS's developed CRPR as rare or endangered with ranks 1A, 1B, 2A, or 2B (defined in the footnotes of **Table 3.5-4**)
- included in the CRPR with ranks 3 or 4 (defined in the footnotes of **Table 3.5-4**)

Using CRPR (2022) and CNDDB (2022) records and other references described at the beginning of the Environmental Setting above, a list of 75 special-status plants known to occur within the general vicinity of the Seismic Retrofit Project Area was compiled. For purposes of assessing potentially occurring plant species, the "general vicinity" included the USGS 7.5-minute quadrangles, including or surrounding the Seismic Retrofit and Conservation Measures Project Areas for CRPR 1-3 species and VHP-covered species, and all the County for CRPR 4 species. These species were then reviewed for their potential to occur in the Project Area. Analysis of the documented habitat requirements and occurrence records associated with all of the special-status plant species considered allowed botanists to reject 62 of these plant species as not having a reasonable potential to occur in the Project Area. A list of all plant species considered but rejected from consideration in the EIR, and the reason for rejection, is provided in Appendix G.

Of the initial list, the remaining 13 plant species were further considered for potential occurrence in the Project Area based on their general habitat requirements and known distributions, and focused surveys for those species were conducted. Valley Water has conducted focused surveys for special-status plants in the Project Area on a number of occasions, including in 2006 and 2008 as part of Valley Water's evaluation of its DMP (Valley Water 2012a) and for the FOCP and the Project in 2013 and 2014 (Valley Water 2014a, 2014b) and in 2017, 2018, and 2021 (Valley Water 2021a ~~2021f~~). As a result, the special-status plants occurring within the Seismic Retrofit Area are well-known, in terms of their distributions and abundance.

Eight of the 13 special-status plant species thought to have some potential for occurrence in the Project Area have been observed within or immediately adjacent to the Seismic Retrofit Area during Valley Water's surveys. These species are Coyote ceanothus, most beautiful jewel-flower, smooth lessingia (*Lessingia micradenia* var. *glabrata*), woodland woollythreads (*Monolopia gracilens*), Mt. Hamilton thistle (*Cirsium* ~~*wainsoni3.5-33*~~ *fontinale* var. *campylon*), Santa Clara Valley dudleya, San Francisco collinsia, and Hall's bush-mallow (*Malacothamnus hallii*). The Existing Conditions Baseline distributions of these eight species in and adjacent to the Seismic Retrofit Area, based on surveys conducted to date and assuming that all areas impacted by the FOCP will remove any special-status species present in those areas, are depicted in **Figure 3.5-8** (Coyote ceanothus) and **Figure 3.5-9** (other species); the lone Hall's bush-mallow plant previously recorded at Anderson Dam has been impacted and is not depicted on those figures. The other five species initially thought to have some potential for occurrence in the Project Area—big-scale balsamroot (*Balsamorhiza macrolepis*), Loma Prieta hoita (*Hoita strobilina*), Tiburon paintbrush, fragrant fritillary (*Fritillaria liliacea*), and Metcalf Canyon jewel-flower—were not detected in the portions of the Seismic Retrofit Area that were surveyed in 2013 and 2014 (Valley Water 2014a, 2014b), and in 2017, 2018, and 2021 (Valley Water 2021a ~~2021f~~). These species are therefore likely absent from the Seismic Retrofit Area. Focused special-status plant surveys have not been performed in the Conservation Measures Project Areas, because, Ogier Ponds CM, based on the suitability of habitat, special-status plants are unlikely to be present in these areas. For example, the Ogier Ponds CM Area and Phase 2 Coyote Percolation Dam Fish Passage Enhancements area are dominated by alluvial deposits, materials excavated from the ponds themselves, disturbed areas, and valley floor riparian and wetland habitats that are not known or expected to support special-status plants. Due to the absence of suitable habitat for special-status plants in those areas, it was determined that no such species would occur there.

This page intentionally left blank.

Table 3.5-4. Special-Status Plant Species Potentially Occurring in the Study Area

Common Name Scientific Name	Regulatory Status	Habitat and Blooming Period	Potential for Occurrence in Study Area
Big-scale balsamroot *Balsamorhiza macrolepis*	CRPR 1B.2	Chaparral, cismontane woodland, valley and foothill grassland sometimes in serpentinite/serpentine bunchgrass grassland, mixed serpentine chaparral, and oak woodland; March-June	**Seismic Retrofit Area: Likely Absent.** Undetected during extensive surveys covering most of the Seismic Retrofit Area; however, there is some potential for occurrence in the limited portions of the Seismic Retrofit Area that were not previously surveyed (**Figure 3.5-10**). Valley Water will conduct surveys for this species in previously unsurveyed portions of the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** No suitable habitat for big-scale balsamroot is present within the Conservation Measures Project Area. **Expanded Study Area: May be Present.** Although there are no known occurrences on Coyote Ridge or other areas that are most likely to be affected by deposition of nitrogen emitted by Project activities, the species occurs southeast of Anderson Reservoir, and it is possible that some individuals may occur in areas where Project-derived nitrogen emissions could be deposited.
Coyote ceanothus *Ceanothus ferrisiae*	FE, CRPR 1B.1, VHP	Chaparral, coastal scrub, and grassland on serpentinite (e.g., serpentine bunchgrass grassland and mixed serpentine chaparral); January-May	**Seismic Retrofit Area: Present.** A focused survey in 2013-2014 identified the distribution and abundance of Coyote ceanothus within the Seismic Retrofit Area, primarily on the right abutment and the north side of Anderson Dam, but with smaller numbers of individuals present on the southeast side as well (Valley Water 2014b). Of the individuals identified during that survey, approximately 853 individuals have since been lost as a result of Project-related geotechnical investigations, dam maintenance activities, and FOCP implementation. A supplemental survey in 2021 identified an additional 424 seedlings and saplings, consisting of 281 south of the dam and 143 north of the dam, that had become established below the reservoir rim since 2017 (the last time the reservoir filled to capacity) due to increased availability of substrate resulting from the drawn down condition of the reservoir (Valley Water 2021a ~~2021f~~). Surveys in January 2023 were conducted to cover limited areas of the Seismic Retrofit Area, as currently proposed, that were not previously surveyed; these surveys identified 61 individuals. Therefore, a total of 2,666 individuals are present in the Seismic Retrofit Area (**Figure 3.5-8**). **Conservation Measures Project Area: Absent.** No suitable habitat for Coyote ceanothus is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Additional Coyote ceanothus are present, primarily north of the Seismic Retrofit Area on Coyote Ridge, in areas that could be affected by dust mobilization from the Project, spread of *Phytophthora*, and deposition of nitrogen emitted by Project activities.
Mt. Hamilton thistle *Cirsium fontinale* var. *campylon*	CRPR 1B.2, VHP	Seeps and streams in chaparral, cismontane woodland, or grassland on serpentinite; April–October	**Seismic Retrofit Area: May be Present.** Special-status plant surveys in 2013-2014 identified 375 individuals in and adjacent to the unlined portion of the spillway (Valley Water 2014a), and another survey by Valley Water in 2019 documented 645 individuals (Valley Water 2019f). Due to impacts from spillway repairs, Project-related geotechnical activities, scour due to reservoir spilling in 2017, and increased density of cattails and pampas grass, no Mt. Hamilton thistle individuals were detected here during a focused survey in 2021 (Valley Water 2021a ~~2021f~~). The 2021 surveys detected a new occurrence of 840 plants along a seep on a steep hillside approximately 0.25 miles east of the spillway (**Figure 3.5-9**). However, those individuals are outside the Project area. Furthermore, no suitable habitat for this species is present in the limited portions of the Seismic Retrofit Area that were not previously surveyed (**Figure 3.5-10**). Although no individuals are currently known to be present in the Seismic Retrofit Area, it is possible that this species still persists (e.g., in the seed bank) along the unlined portion of the spillway, and therefore it may be present. **Conservation Measures Project Area: Absent.** No suitable habitat for Mt. Hamilton thistle is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Additional Mt. Hamilton thistles are present, primarily north of the Seismic Retrofit Area on Coyote Ridge, in areas that could be affected by deposition of nitrogen emitted by Project activities, and an occurrence along the edge of the reservoir northeast of the dam could be affected by dust mobilization.
San Francisco collinsia *Collinsia multicolor*	CRPR 1B.2	Closed-cone coniferous forest and coastal scrub, sometimes on serpentinite; March-May	**Seismic Retrofit Area: Likely Absent.** Although a population is present on an eroding serpentine slope along the shoreline of Anderson Reservoir, as described for the expanded study area below, this species has not been detected during extensive surveys within the Seismic Retrofit Area. However, there is some potential for occurrence in the limited portions of the Seismic Retrofit Area that were not previously surveyed (**Figure 3.5-10**). Valley Water will conduct surveys for this species in previously unsurveyed portions of the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** No suitable habitat for San Francisco collinsia is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Valley Water has been monitoring the abundance and distribution of a San Francisco collinsia population on an eroding serpentine slope along the shoreline of Anderson Reservoir since it was discovered by a Valley Water

Common Name Scientific Name	Regulatory Status	Habitat and Blooming Period	Potential for Occurrence in Study Area
			botanist in 2009 ~~(Valley Water 2012d).~~ This occurrence is located along a 0.25-miles segment of the southwest shoreline approximately 0.2 to 0.4 miles northeast of the top of the boat ramp near the dam (**Figure 3.5-9**). Since the initial detection of 300 individuals in 2009, abundance has fluctuated from year to year. After the reservoir filled during heavy storms in February 2017, only 591 individuals were tallied that spring, although the population recovered to a high of 6,668 individuals in 2021. A total of 4,852 individuals were counted in 2022. This population has averaged 3,358 individuals, spread over an area of approximately 0.67 acres, since complete population surveys began in 2011. The majority of these individuals are present below the reservoir rim (e.g., in areas that are inundated when the reservoir is filled).
Santa Clara Valley dudleya *Dudleya abramsii* ssp. *setchellii* ~~*Setchellii*~~	FE, CRPR 1B.1, VHP	Rocky outcrops in cismontane woodland, chaparral, and grassland on serpentinite; April-October	**Seismic Retrofit Area: Absent.** Special-status plant surveys in 2013-2014 identified 144 individuals on rock outcrops on and around Silica Carbonate Hill, east of the spillway (Valley Water 2014a). The construction footprint for the Seismic Retrofit Area extends to the base of these outcrops but does not include any areas occupied by Santa Clara Valley dudleya. Furthermore, no suitable habitat for this species is present in the limited portions of the Seismic Retrofit Area that were not previously surveyed (**Figure 3.5-10**). Therefore, no individuals are currently present in the Seismic Retrofit Area, although they are present immediately adjacent to this area. **Conservation Measures Project Area: Absent.** No suitable habitat for Santa Clara Valley dudleya is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** The 144 individuals detected on rock outcrops on and around Silica Carbonate Hill, east of the spillway, during 2013-2014 surveys are immediately adjacent to the Seismic Retrofit Area (Valley Water 2014a). Additional Santa Clara Valley dudleya are present, primarily north of the Seismic Retrofit Area on Coyote Ridge, in areas that could be affected by deposition of nitrogen emitted by Project activities.
Smooth lessingia *Lessingia micradenia* var. *glabrata*	CRPR 1B.2, VHP	Grasslands or open, often recently disturbed, areas in chaparral, coastal scrub, and cismontane woodland on serpentinite; July-November	**Seismic Retrofit Area: Present.** Special-status plant surveys in 2013-2014 identified approximately 3,200 individuals in scattered locations within the surveyed area (Valley Water 2014a). Most individuals were on the north side of Silica Carbonate Hill, though smaller numbers were present just northeast of the spillway, on the right abutment, and on slopes above the boat ramp and the BHBA. Follow-up surveys in 2021 detected lessingia in these same areas, finding that populations had expanded and increased in abundance (Valley Water 2021a ~~2021f~~). Approximately 1,921 individuals are known to be present within the Seismic Retrofit Area, above the reservoir rim. Suitable habitat for this species is also present in the limited portions of the Seismic Retrofit Area that were not previously surveyed (**Figure 3.5-10**), and Valley Water will conduct surveys for this species in previously unsurveyed portions of the Seismic Retrofit Area. This species has also colonized serpentine-based substrate below the reservoir rim due to the drawn down condition of the reservoir. **Conservation Measures Project Area: Absent.** No suitable habitat for smooth lessingia is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Additional smooth lessingia are present, primarily north of the Seismic Retrofit Area on Coyote Ridge, in areas that could be affected by dust mobilization from the Project, spread of *Phytophthora*, and deposition of nitrogen emitted by Project activities.
Hall's bush-mallow *Malacothamnus hallii*	CRPR 1B.2	Chaparral and coastal scrub, sometimes on serpentinite; May-September	**Seismic Retrofit Area: Absent.** A single individual was identified in the northern coastal scrub/Diablan sage scrub within the Project Area, along the paved road on the right abutment, during the 2006/2008 surveys for the DMP (Valley Water 2012a). During protocol-level surveys of the Seismic Retrofit Area in 2013-2014 (Valley Water 2014a) and follow-up surveys in 2017 and 2018 of additional areas added later, this single individual was the only one detected in the Seismic Retrofit Project Area. This individual was impacted by FOCP activities. Furthermore, no suitable habitat for this species is present in the limited portions of the Seismic Retrofit Area that were not previously surveyed (**Figure 3.5-10**). Therefore, no individuals are currently present in the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** No suitable habitat for Hall's bush-mallow is present within the Conservation Measures Project Area. **Expanded Study Area: Absent.** No suitable habitat for Hall's bush-mallow is present within portions of the study area outside the Project Area.
Woodland woollythreads *Monolopia gracilens*	CRPR 1B.2	Grasslands or open areas in chaparral, coastal scrub, cismontane woodland, and North Coast coniferous forest on serpentinite; March-July	**Seismic Retrofit Area: Present.** Special-status plant surveys in 2013-2014 detected a large population, totaling approximately 112,800 plants, in openings within mixed serpentine chaparral north and northeast of the spillway, with a few individuals present in foothill pine-oak woodland and northern coastal scrub/Diablan sage scrub in and adjacent to the unlined portion of the spillway and in the Chert Hill quarry (Valley Water 2014a). That large population had colonized open areas after a fire on Pigeon Point in 2003, upslope from the spillway, cleared extensive areas of woody vegetation. Succession has since resulted in the re-establishment and expansion of trees and shrubs, filling and shading the gaps that were occupied by woollythreads in 2013-2014, so that the 2021 surveys identified

Common Name Scientific Name	Regulatory Status	Habitat and Blooming Period	Potential for Occurrence in Study Area
			only 3,500 plants in the same areas (Valley Water 2021a ~~2021f~~). Approximately 1,142 individuals are known to be present within the Seismic Retrofit Area, all north or northeast of the lined and unlined portions of the spillway. Suitable habitat for this species is also present in the limited portions of the Seismic Retrofit Area that were not previously surveyed (**Figure 3.5-10**), and Valley Water will conduct surveys for this species in previously unsurveyed portions of the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** No suitable habitat for woodland woollythreads is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Additional woodland woollythreads are present, primarily north of the Seismic Retrofit Area on Coyote Ridge, in areas that could be affected by dust mobilization from the Project, spread of *Phytophthora*, and deposition of nitrogen emitted by Project activities.
Most beautiful jewel-flower *Streptanthus albidus* ssp. *Peramoenus* ~~*peramoenus*~~	CRPR 1B.2, VHP	Grasslands or open areas in chaparral, coastal scrub, or cismontane woodland on serpentinite (e.g., serpentine bunchgrass grassland and mixed serpentine chaparral); April-September	**Seismic Retrofit Area: Present.** Special-status plant surveys in 2013-2014 detected 86 individuals, all in a limited area on the north side of the Chert Hill quarry (Valley Water 2014a). Follow-up surveys in 2021 detected 86 plants in the same area, as well as four individuals immediately north of the concrete-lined portion of the spillway (Valley Water 2021a ~~2021f~~). Approximately four individuals are known to be present within the Seismic Retrofit Area, all immediately north of the spillway. Suitable habitat for this species is also present in the limited portions of the Seismic Retrofit Area that were not previously surveyed (**Figure 3.5-10**), and Valley Water will conduct surveys for this species in previously unsurveyed portions of the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** No suitable habitat for most beautiful jewel-flower is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Additional most beautiful jewel-flowers are present, primarily north of the Seismic Retrofit Area on Coyote Ridge, in areas that could be affected by dust mobilization from the Project, spread of *Phytophthora*, and deposition of nitrogen emitted by Project activities.
Metcalf Canyon jewel-flower *Streptanthus albidus* ssp. ~~*Albidus*~~ *albidus*	FE, CRPR 1B.1, VHP	Serpentine grasslands; April-July	**Seismic Retrofit Area: Likely Absent.** Undetected during extensive surveys; not expected to occur in the limited portions of the Seismic Retrofit Area that were not previously surveyed, as all known occurrences are far to the northwest of the Seismic Retrofit Area, which is therefore outside the species' range. Nevertheless, Valley Water will conduct surveys for this species in previously unsurveyed portions of the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** No suitable habitat for Metcalf Canyon jewel-flower is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Present, primarily north of the Seismic Retrofit Area on Coyote Ridge, in areas that could be affected by deposition of nitrogen emitted by Project activities.
Tiburon paintbrush *Castilleja affinis* ssp. *neglecta* ~~*Neglecta*~~	FE, ST, CRPR 1B.2, VHP	Serpentine grasslands; April-June	**Seismic Retrofit Area: Likely Absent.** Undetected during extensive surveys; not expected to occur in the limited portions of the Seismic Retrofit Area that were not previously surveyed due to the absence of high-quality habitat. Nevertheless, Valley Water will conduct surveys for this species in previously unsurveyed portions of the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** No suitable habitat for Tiburon paintbrush is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Two populations are present north of the Seismic Retrofit Area on Coyote Ridge, in areas that could be affected by deposition of nitrogen emitted by Project activities.
Loma Prieta hoita *Hoita strobilina*	CRPR 1B.1, VHP	Chaparral, cismontane woodland, and riparian woodland, usually on serpentinite; May-July	**Seismic Retrofit Area: Likely Absent.** Undetected during extensive surveys covering most of the Seismic Retrofit Area; however, there is some potential for occurrence in the limited portions of the Seismic Retrofit Area not previously surveyed. Valley Water will conduct surveys for this species in previously unsurveyed portions of the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** No suitable habitat for Loma Prieta hoita is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Present, primarily north of the Seismic Retrofit Area on Coyote Ridge, in areas that could be affected by deposition of nitrogen emitted by Project activities.

Common Name **Scientific Name**	**Regulatory Status**	**Habitat and Blooming Period**	**Potential for Occurrence in Study Area**
Fragrant fritillary *Fritillaria liliacea*	CRPR 1B.2, VHP	Cismontane woodland, coastal prairie, coastal scrub, and grassland, often on serpentinite; February-April	**Seismic Retrofit Area: Likely Absent.** Undetected during extensive surveys covering most of the Seismic Retrofit Area; however, there is some potential for occurrence in the limited portions of the Seismic Retrofit Area that were not previously surveyed. Valley Water will conduct surveys for this species in previously unsurveyed portions of the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** No suitable habitat for fragrant fritillary is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Present, primarily north of the Seismic Retrofit Area on Coyote Ridge but also directly east of the BHBA, in areas that could be affected by deposition of nitrogen emitted by Project activities.
Alkali milk vetch *Astragalus tener* var. *tener*	CRPR 1B.2	Playas, clay soils supporting valley and foothill grasslands, and alkaline, vernal pools; March-June	**Seismic Retrofit Area: Absent.** No suitable habitat, outside the species' range. **Conservation Measures Project Area: Absent.** No suitable habitat, outside the species' range. **Expanded Study Area: Low Likelihood of Presence.** Although likely absent, there is at least a low potential for this species to occur in tidal salt marshes along Coyote Slough that could be affected by increased frequency and magnitude of flows, and sediment mobilization, during Project construction.
Point Reyes bird's beak *Cordylanthus maritimus* ssp. *palustris Palustris*	CRPR 1B.2	Salt marshes, particularly at salt pan edges with occasional tidal inundation; June-October	**Seismic Retrofit Area: Absent.** No suitable habitat, outside the species' range. **Conservation Measures Project Area: Absent.** No suitable habitat, outside the species' range. **Expanded Study Area: Low Likelihood of Presence.** Although likely absent, there is at least a low potential for this species to occur in tidal salt marshes along Coyote Slough that could be affected by increased frequency and magnitude of flows, and sediment mobilization, during Project construction.

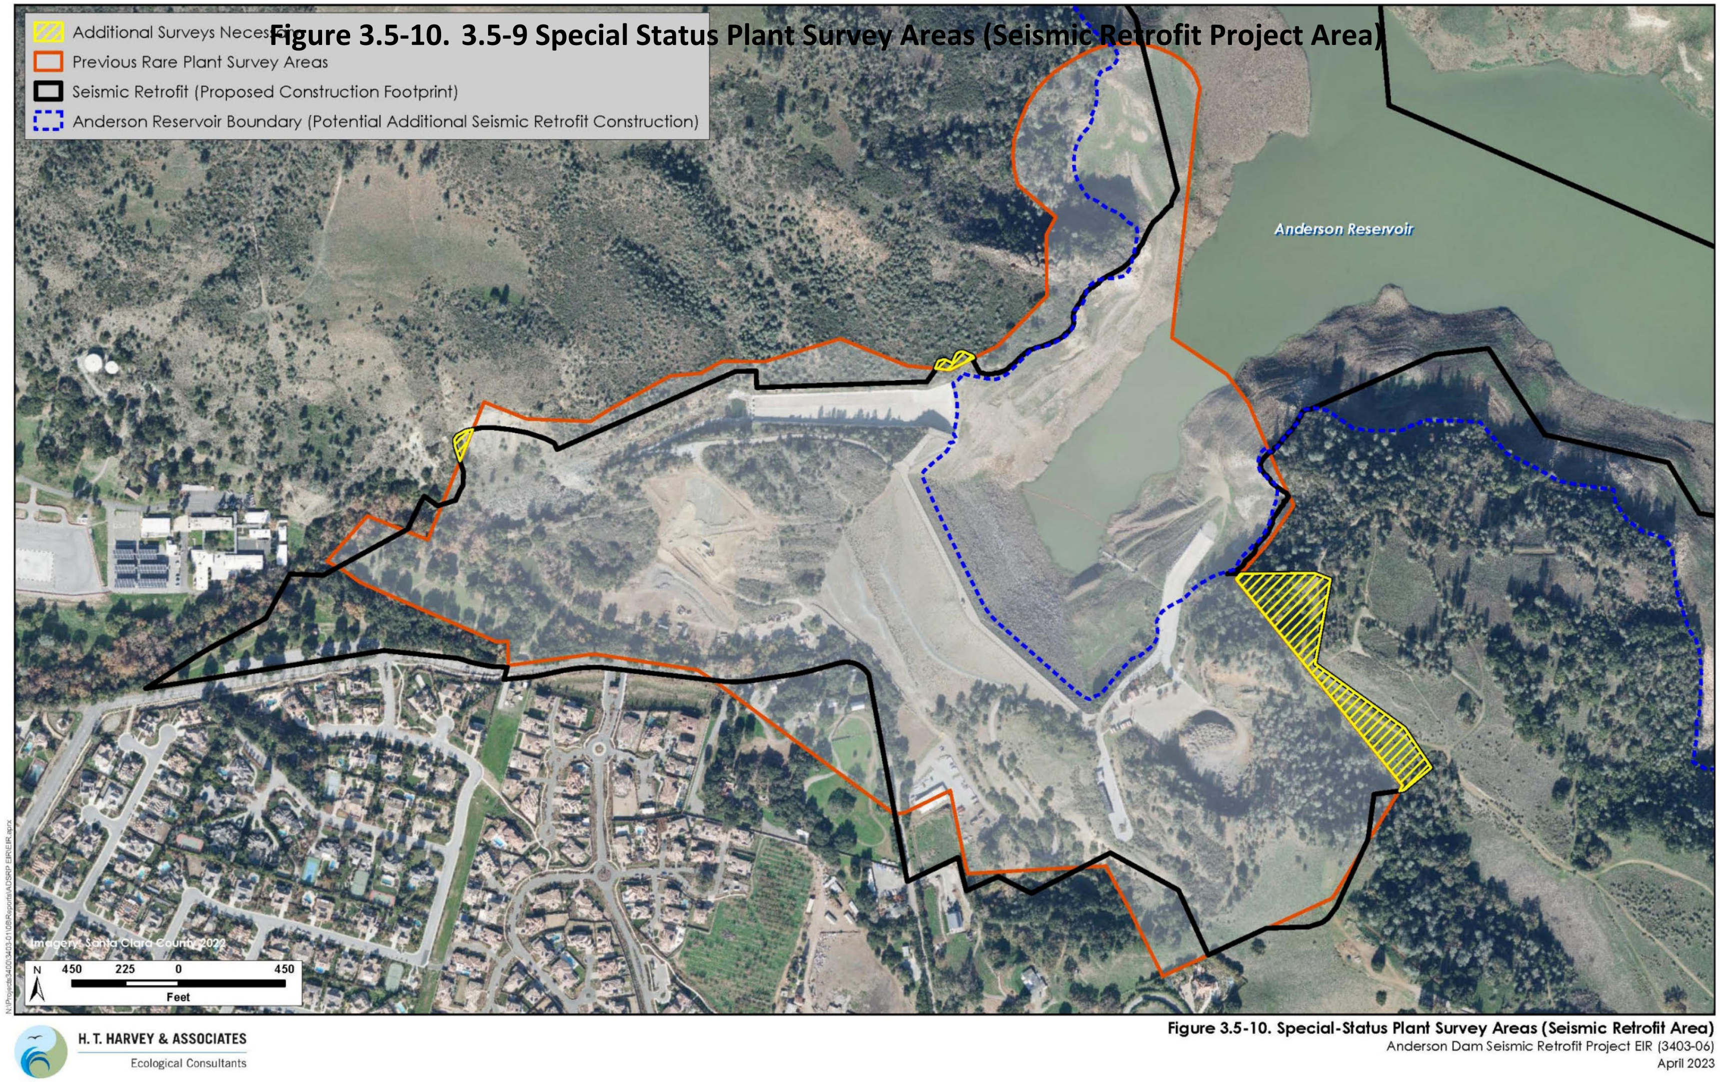
Figure 3.5-10. 3.5-9 Special Status Plant Survey Areas (Seismic Retrofit Project Area)



In addition, the potential for special-status plant species to occur in the remaining portions of the study area, and that could therefore be affected by Project activities as described in *Habitat Conditions and Characteristic Species in Other Impact Areas*, was considered. Six of the special-status plant species known to occur in or immediately adjacent to the Seismic Retrofit Area—Coyote ceanothus, Mt. Hamilton thistle, Santa Clara Valley dudleya, smooth lessingia, woodland woollythreads, and most beautiful jewel-flower—also occur on Coyote Ridge or other areas where they could be affected by nitrogen emissions from the Project. Five additional serpentine-associated special-status plant species that are likely absent from the Project Area occur in areas where they could be affected by nitrogen emissions from the Project. Tiburon paintbrush, Metcalf Canyon jewelflower, Loma Prieta hoita, and fragrant fritillary are known to occur in serpentine-influenced plant communities on Coyote Ridge and, in the case of fragrant fritillary, just outside the Seismic Retrofit Area northeast of the BHBA, whereas big-scale balsamroot occurs southeast of Anderson Reservoir (CNDDB 2022).

No special-status plants are known or expected to be present in the portion of the study area along Coyote Creek from Anderson Dam downstream to baylands areas, or in riparian or stream habitats along Upper Penitencia Creek where fish relocation may occur. However, tidal wetlands that could be subject to increased flows or sediment deposition during Project construction or as a result of increased post-construction flows could support two special-status plant species: alkali milk vetch (*Astragalus tener* var. *tener*) and Point Reyes bird's beak (*Cordylanthus maritimus* ssp. *Palustris*). Although there are no recent records of these species in or near the far South Bay, they occur in the types of tidal marsh habitats that could be affected by Project activities. Another tidal marsh species, California seablite (*Suaeda californica*), occurs in San Francisco Bay only in a few well-known populations well north of the mouth of Coyote Slough and is therefore absent from the Project's study area. Another special-status plant, Congdon's tarplant (*Centromadia parryi* ssp. *Congdonii*), is known to occur in several locations in the South Bay, but in nontidal alkali grasslands and ruderal habitats that would not be impacted by Project-related increases in flows or sediment deposition. Special-status plants have not been recorded, and are not expected to occur, in wetland, aquatic, or riparian habitats in North Coyote Valley that could be affected by changes in groundwater levels during Project construction (H. T. Harvey & Associates 2019a ~~2019b~~).

Table 3.5-4 discusses all special-status plant species known or expected to occur in the study area where, based on the nature of Project activities and how they could impact each of those species. For example, of all the potentially occurring special-status plants in the study area, serpentine-associated plants are the species that are most susceptible to effects of nitrogen deposition. As a result, areas subject to deposition of emitted nitrogen were considered impact areas only for serpentine-associated plants.

Special-Status Wildlife

Special-status animals that may occur in the study area, including not only the Project Area but also other areas that could be impacted by Project activities (i.e., the expanded study area), are discussed in **Table 3.5-5**. For purposes of this analysis, special-status wildlife includes animal species that meet at least one of the following criteria:

- listed under ESA as threatened, endangered, proposed as threatened, proposed as endangered, or a candidate species for listing
- listed under CESA as threatened, endangered, or a candidate species for listing

- designated by CDFW as a California Species of Special Concern (SSC)
- designated in the Fish and Game Code as a fully protected species (birds at Section 3511, mammals at Section 4700, reptiles and amphibians at Section 5050, and fish at Section 5515)

All special-status animal species potentially occurring in the Seismic Retrofit Area, the Conservation Measures Project Area, and the expanded study area were considered. First, a list of 45 special-status animals known to occur within the general vicinity of the Seismic Retrofit Area and Conservation Measures Project Area was compiled using the materials described at the beginning of the Environmental Setting above (e.g., CNDDB records, the VHP, and documents prepared for the FOCP, DMP, and SMP). These species were then reviewed for their potential to occur in the Seismic Retrofit Area and the Conservation Measures Project Area. Analysis of the documented habitat requirements and occurrence records associated with all the species considered allowed consultant wildlife ecologists to reject 14 of these species as not having a reasonable potential to occur in these areas.

In addition to assessing the potential for special-status animals to occur in the Seismic Retrofit Area and/or the Conservation Measures Project Area, the potential for special-status wildlife species to occur in the expanded study area where they could be affected by Project activities as described in *Habitat Conditions and Characteristic Species in Other Impact Areas* was also considered. One serpentine-associated special-status animal species that is likely absent from (or could occur only sparingly in) the Seismic Retrofit Area, Bay checkerspot butterfly occurs in areas where it could be affected by nitrogen emissions from the Project. Several special-status animals that occur in the Project Area could occur in wetland, aquatic, or riparian habitats in North Coyote Valley that could be affected by changes in groundwater levels during Project construction, and several similarly occur along Upper Penitencia Creek where steelhead relocation may be necessary. A number of additional special-status animals are absent from the Seismic Retrofit Area and Conservation Measures Project Area but occur in baylands ~~3.5-43~~ areas that could be subject to increased flows or sediment deposition during Project construction or as a result of increased post-construction flows.

Table 3.5-5. Special-Status Animal Species Potentially Occurring in Study Area

Common Name Scientific Name	Regulatory Status	Habitat	Potential for Occurrence in Study Area
Federal or State Endangered, Threatened, or Candidate Species			
Bay checkerspot butterfly *Euphydryas editha bayensis*	FE, VHP	Native grasslands on serpentine soils. Larval host plants are *Plantago erecta* and/or *Castilleja* sp.	**Seismic Retrofit Area: Low Likelihood of Presence.** Unlikely to occur on Anderson Dam itself, but present on Coyote Ridge north of the dam. Known to occur in the vicinity of Kirby Canyon landfill along Coyote Ridge, approximately 2 miles northwest of the Seismic Retrofit Area; however, additional unidentified occurrences of the species may also extend south of Kirby Canyon toward the Seismic Retrofit Area along lands under private ownership that have not yet been surveyed for the species. Four small, isolated areas at the dam support populations of its larval host plant, foothill plantain, but are considered unsuitable due to their very limited extent. Designated critical habitat Unit 13 extends southward along Coyote Ridge to the northern edge of the dam, overlapping areas along the north side of the spillway; approximately 2.6 acres of designated critical habitat for the species is present in the Seismic Retrofit Area. In addition, the VHP maps the grassland southeast of the dam, on Santa Clara County Parks property, as a Bay checkerspot population, “occupancy unknown.” A survey for adults was conducted on April 19, 2014, in all areas of the Seismic Retrofit Area providing potential habitat for the species, but no individuals were detected, and the species has not been observed there during numerous other biological surveys. If the species occurs in the Seismic Retrofit Area, it does so infrequently and/or in low numbers. **Conservation Measures Project Area: Absent.** No suitable habitat for the Bay checkerspot butterfly is present within the Conservation Measures Project Area. **Expanded Study Area: Present.** Large populations are present, primarily north of the Seismic Retrofit Area on Coyote Ridge (but also to the southeast at Harvey Bear Ranch County Park), in areas that could be affected by deposition of nitrogen emitted by Project activities.
Monarch butterfly *Danaus plexippus*	FPT ~~FC~~	Larval host plants are typically milkweeds (*Asclepias* spp.); nectars on a variety of flowering plants	**Seismic Retrofit Area: Present.** Occurs widely as an uncommon migrant, nectaring on flowering plants. Narrow-leaf milkweed (*Asclepias fascicularis*) is present in scattered patches within the Seismic Retrofit Area, and monarchs could breed in low numbers. Close examination of approximately 480 clusters of milkweed plants along Coyote Creek between Anderson Dam and the Coyote Creek Golf Course area (including the Ogier Ponds) on 3 days in May and June 2022 detected only two monarch butterfly larvae; inspection of 100 plants along the rim of Anderson Reservoir on July 30, 2022, detected no monarch eggs, larvae, or pupae (S. Rottenborn, personal observation), and examination of another 300 milkweed plants along the reservoir rim in July and August 2024 revealed only one monarch larva. Thus, although monarch butterflies do breed in the Project vicinity, they do so in low numbers, breeding much less commonly than is indicated by the abundance of their host plant. No large wintering aggregations occur in Santa Clara County. **Conservation Measures Project Area: Present.** Occurs widely as an uncommon migrant, nectaring on flowering plants. Narrow-leaf milkweed is present in scattered patches at the Ogier Ponds; monarch butterfly has been detected breeding on milkweed at the downstream-most end of the Ogier Ponds complex and likely breeds in low numbers at this site. **Expanded Study Area: Present.** Occurs widely as an uncommon migrant, nectaring on flowering plants. Along Coyote Creek downstream from Anderson Dam, this species has been detected breeding on milkweed near Coyote Creek Golf Drive, and it likely breeds in low numbers where milkweed is present.
Crotch’s bumble bee *Bombus crotchii*	SC	Open grassland and scrub habitats	**Seismic Retrofit Area: Present.** Although the species was historically found throughout the southern two-thirds of California, population declines and range contractions have ~~made this species very scarce~~ reduced this species’ abundance in parts of the state. ~~region~~. Since 2019, there have been documented occurrences of more than 100 individuals from approximately 20 locations in Santa Clara County (Bumble Bee Watch 2024, iNaturalist 2022, S. Lockwood and S. Rottenborn, pers. obs.), indicating that the species is still extant, and fairly widespread, in the County ~~From 2019 to 2021, single individuals were recorded in five scattered locations in Santa Clara County, including Coyote Lake Harvey Bear Ranch, south of Anderson Reservoir (iNaturalist 2022).~~. Surveys for this species in July 2022 detected one individual foraging on bull thistle along the San Felipe Creek channel in the northwest arm of drawn-down Anderson Reservoir and at least three individuals south of the Project Area at the upper end of Coyote Reservoir, and small numbers have been recorded on Coyote Ridge west and northwest of the reservoir (Bumble Bee Watch 2024 ~~S. Rottenborn, personal observation~~). This species likely occurs in grassland and scrub habitat, including the bed of the drawn-down reservoir, in low numbers. **Conservation Measures Project Area: Moderate Likelihood of Presence.** Due to the low abundance of this species in the region, it likely does not occur commonly anywhere, but it could occur in low numbers in grassland at the Ogier Ponds. **Expanded Study Area: Moderate Likelihood of Presence.** Due to the low abundance of this species in the region, it likely does not occur commonly anywhere, but it could occur in low numbers near grassland along Coyote Creek downstream from Anderson Dam.

Common Name Scientific Name	Regulatory Status	Habitat	Potential for Occurrence in Study Area
California tiger salamander *Ambystoma californiense*	FT, ST, VHP	Breeds in vernal or temporary pools in annual grasslands or open woodlands; spends most time in subterranean refugia, such as small mammal burrows or deep rock crevices	**Seismic Retrofit Area: Present.** In 2001, one was observed on Anderson Dam ~~dam~~ (CNDDB 2022). In 2011, one was found during a routine pre-work biological inspection in a weep hole in the floor of the dam spillway (Valley Water 2012a). In March 2016, an individual was found in a drain near the top of the boat ramp. A large seasonal pond (Rosendin Pond) 0.3 miles southeast of the dam (approximately 500 feet southeast of the Seismic Retrofit Area boundary at Basalt Hill) is a known breeding pond (CNDDB 2022). This species may also breed in a small perennial pond approximately 90 feet south of the Seismic Retrofit Area, near the park entrance road off Cochrane Road. Individuals could move through the Seismic Retrofit Area or use mammal burrows and crevices as refugia. However, inspections of burrows on the dam face from 2010 to 2013 found no individuals (Valley Water 2010a, 2011b ~~2011a~~, 2012d ~~2012c~~, 2013). Thus, California tiger salamanders are known to occur in and near the dam and reservoir portions of the Seismic Retrofit Area, although they likely do so infrequently and in low numbers given the paucity of records near the dam. The “reservoir” land cover type is not considered suitable for this species (ICF 2012), though individuals may disperse into the bed of the dewatered reservoir. **Conservation Measures Project Area: Likely Absent.** The Ogier Ponds are unlikely to support a breeding population of California tiger salamanders due to the abundance of predatory bullfrogs, fish, and crayfish. Surveys conducted in 2019 in a group of ponds that are not in-line with Coyote Creek (and that therefore had the highest likelihood of supporting California tiger salamander) did not detect the species (Valley Water 2019b ~~2019e~~). For the same reasons, California tiger salamanders are unlikely to breed in the Parkway Lakes ponds or the Coyote Percolation Pond, near the location of the proposed Coyote Percolation Dam CM. There is a low potential for California tiger salamanders to disperse from breeding sites to the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach areas. **Expanded Study Area: Present.** California tiger salamanders have bred in ponds in North Coyote Valley south of Bailey Avenue and west of Santa Teresa Boulevard for at least several decades (H. T. Harvey & Associates 2019a ~~2019b~~, 2021, 2022), and additional suitable breeding habitat is present north of Bailey Avenue.
California red-legged frog *Rana draytonii*	FT, CSSC, VHP	Streams, freshwater pools, and ponds with emergent or overhanging vegetation	**Seismic Retrofit Area: Present.** California red-legged frogs do not breed in Anderson Reservoir, which is not considered suitable habitat for the species (ICF 2012), though red-legged frogs may disperse into the bed of the dewatered reservoir. Critical habitat Unit STC-1 is located immediately northeast of Anderson Reservoir (USFWS 2010). At Anderson Dam itself, California red-legged frogs have been observed in only one area—three adults were observed in cattail-lined pools within the unlined portion of the spillway, downstream from the concrete spillway, during monitoring associated with geotechnical investigations in June 2020; two of these individuals were relocated to Rosendin Pond to prevent injury during the geotechnical work (the third individual moved out of the work area on its own). The pools in the unlined spillway are unlikely to support a viable breeding population of red-legged frogs due to the abundance of nonnative bullfrogs and fish, which may prey on red-legged frog eggs or larvae, but the species could attempt breeding in the unlined spillway chute. The pools below the spillway waterfall and a small perennial pond approximately 90 feet south of the Seismic Retrofit Area could also support breeding attempts by California red-legged frogs. Suitable breeding habitat for red-legged frogs is present in Rosendin Pond, 0.3 miles southeast of the dam spillway and approximately 500 feet southeast of Basalt Hill, and the species likely breeds there (CNDDB 2022). California red-legged frogs could also use small mammal burrows and crevices present throughout the action area as refugia. However, because no individuals were found during burrow scoping surveys on the dam during four years of surveys (Valley Water 2010a, 2011b ~~2011a~~, 2012d ~~2012c~~, 2013), this species uses such upland refugia infrequently and in low numbers, if at all. **Conservation Measures Project Area: Present.** California red-legged frog adults and tadpoles were reported at an unspecified location in the Ogier Ponds in 2002 (CNDDB 2022). The Ogier Ponds provide ostensibly suitable habitat for breeding California red-legged frog, but bullfrogs (and fish in some ponds) are abundant, making the Ogier Ponds unlikely to support a viable California red-legged frog population. This species was not detected during baseline surveys, including both daytime and nighttime surveys, at the Ogier Ponds or elsewhere along Coyote Creek downstream of Anderson Dam in 2019 (Valley Water 2019b ~~2019e~~). Thus, California red-legged frogs are not expected to occur in Coyote Creek below Anderson Dam, including at the Ogier Ponds, Coyote Percolation Dam, Live Oak Restoration Reach, or North Channel Reach ~~Extension~~ area, except as rare dispersants. **Expanded Study Area: Present.** California red-legged frogs are known to occur in Upper Penitencia Creek where steelhead relocation may be necessary (CNDDB 2022), and that reach of creek is located within critical habitat Unit STC-1 (USFWS 2010). California red-legged frogs could occur along Coyote Creek downstream from Anderson Dam as infrequent dispersants, though the species is likely absent from more urban segments of the creek. Although the species has been recorded on either side of Coyote Valley, there are no records of the species on the valley floor apart from the 2002 record from the Ogier Ponds. For example, a number of surveys for the species have been conducted along Fisher Creek and in ponds in North Coyote Valley, yet the species has not been detected (H. T. Harvey & Associates 2000a, b, c ~~2000b, c,e~~, 2006a,b, 2007a,b, 2020, 2021, 2022).

Common Name Scientific Name	Regulatory Status	Habitat	Potential for Occurrence in Study Area
Foothill yellow-legged frog *Rana boylii*	FT ~~FC~~, SE, VHP	Partially shaded shallow streams and riffles with a rocky, usually cobbly, substrate. Occurs in a variety of habitats in coast ranges.	**Seismic Retrofit Area: Low Likelihood of Presence.** This species has been extirpated from valley-floor areas of Santa Clara County and is not known to be extant along the county's streams below major reservoirs (Valley Water 1999). It has been recorded in Otis Creek, a tributary to the reach of Coyote Creek between Coyote Dam and Anderson Reservoir (D. Bell, pers. Comm.). However, baseline surveys performed upstream of Anderson Reservoir in Coyote Creek did not detect any individuals of the species (Valley Water 2016). This reach, between the two reservoirs, is unlikely to support a viable breeding population of foothill yellow-legged frogs due to the effects of bullfrog presence both in Anderson Reservoir and in reaches of Coyote Creek upstream of the reservoir (Kupferberg 1996, Adams et al. 2017), as well as the effects of the upstream Coyote Creek Dam (Kupferberg et al. 2012). A survey for the species conducted in April, May, and June 2019 downstream from Anderson Dam, focusing on areas providing the most suitable conditions for the species, also did not detect any individuals (Valley Water 2019b ~~2019e~~). Although there is some potential for a foothill yellow-legged frog to disperse downstream into the dewatered bed of Anderson Reservoir, the lack of a breeding population very nearby and the unsuitable nature of the substrate in the Coyote Creek bed within the drawn-down reservoir (being sandy and silty rather than cobbly) minimize the potential for this species to occur anywhere in the Seismic Retrofit Area. **Conservation Measures Project Area: Absent.** This species has been extirpated from valley-floor areas of Santa Clara County and is not known to be extant along the County's streams below major reservoirs (Valley Water 1999), and a survey for the species conducted in April, May, and June 2019 downstream from Anderson Dam, focusing on areas providing the most suitable conditions for the species, also did not detect any individuals (Valley Water 2019b ~~2019e~~). **Expanded Study Area: Present.** Foothill yellow-legged frog has been recorded in Upper Penitencia Creek where steelhead relocation may be necessary (CNDDB 2022).
~~Western~~ Northwestern pond turtle *Actinemys marmorata ~~pallida~~*	FPTC, CSSC, VHP	Occurs in ponds, streams, and other wetland habitats in the Pacific slope drainages of California. Ponds or slack-water pools with suitable basking sites (such as logs) are an important habitat component for this species, and northwestern pond turtles do not occur commonly along high-gradient streams. Females lay eggs in upland habitats, in clay or silty soils in unshaded (often south-facing) areas. Nesting habitat is typically found within 600 feet of aquatic habitat.	**Seismic Retrofit Area: Present.** There is a 2001 CNDDB record of northwestern pond turtle from Anderson Reservoir (CNDDB 2022), and one was observed in a pond below the spillway waterfall in 2013 (S. Rottenborn, personal observation). However, no individuals have been observed in the reservoir during numerous surveys around the dam (e.g., preactivity surveys for geotechnical investigations performed for the Project) since 2013, and monthly surveys of the entire drawn-down reservoir April-July 2021 and March-July 2022 have detected no individuals. This species has been observed in Coyote Creek immediately downstream from Anderson Dam, though it is far outnumbered by nonnative red-eared sliders. **Conservation Measures Project Area: Present.** This species has been observed at scattered locations along Coyote Creek from Anderson Dam downstream to the Coyote Percolation Dam, including the Ogier Ponds, during focused surveys conducted in 2019 (Valley Water 2019b ~~2019e~~) and during monthly monitoring in spring and summer 2021 and 2022 for the FOCP. It could also be present in the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach areas. **Expanded Study Area: Present.** This species is present in Coyote Creek downstream from Anderson Dam, with observations downstream to the upper limits of tidal influence. It may also be present in Upper Penitencia Creek, where steelhead relocation may occur. Intensive surveys for this species in North Coyote Valley waterbodies have not detected it there.
California Ridgway's rail *Rallus obsoletus obsoletus*	FE, SE, SP	Tidal salt marsh dominated by cordgrass and pickleweed; occasionally occurs in brackish marshes as well	**Seismic Retrofit Area: Absent.** Suitable habitat is absent, and the Seismic Retrofit Area is outside the species' range. **Conservation Measures Project Area: Absent.** Suitable habitat is absent, and the Conservation Measures Project Area is outside the species' range. **Expanded Study Area: Present.** This species breeds in tidal brackish and salt marshes along Coyote Creek/Coyote Slough from the vicinity of Newby Island downstream to the mouth of Coyote Slough.
California black rail *Laterallus jamaicensis coturniculus*	ST, SP	Breeds in fresh, brackish, and tidal salt marsh near the edge of San Francisco Bay	**Seismic Retrofit Area: Absent.** Suitable habitat is absent, and the Seismic Retrofit Area is outside the species' range. **Conservation Measures Project Area: Absent.** Suitable habitat is absent, and the Conservation Measures Project Area is outside the species' range. **Expanded Study Area: Present.** This species breeds in tidal brackish and salt marshes along Coyote Creek/Coyote Slough from the vicinity of Newby Island downstream to the mouth of Coyote Slough.
California least tern *Sternula antillarum browni*	FE, SE, SP	Nests along the coast on bare or sparsely vegetated, flat substrates; in the South Bay, nests in salt pannes and on an old airport runway; forages for fish in open waters	**Seismic Retrofit Area: Absent.** Suitable habitat is absent, and the Seismic Retrofit Area is outside the species' range. **Conservation Measures Project Area: Absent.** Suitable habitat is absent, and the Conservation Measures Project Area is outside the species' range. **Expanded Study Area: Absent when impacts may occur.** There are no records of the species foraging in Coyote Slough; when this species is observed near Coyote Slough, it is seen foraging in managed ponds and over the more extensive open bay. Although least terns could forage on occasion in Coyote Slough, they likely do so infrequently and in low numbers. Least terns do not nest in Project impact areas, and do not roost in habitats that could be adversely affected by increased flows or sediment deposition that may occur during Project construction. The California least tern is absent from the region from October through March, and although the eBird database contains hundreds of records of

Common Name Scientific Name	Regulatory Status	Habitat	Potential for Occurrence in Study Area
			the species from Santa Clara County July into September, there are only four records from April through June (Cornell Lab of Ornithology 2022). Thus, during the wet season, when effects of increased flows, sediment mobilization, and increased post-construction releases from Anderson Reservoir could occur, least terns are absent from Project impact areas.
Bald eagle *Haliaeetus leucocephalus*	SE, SP	Occurs mainly along seacoasts, rivers, and lakes; nests in tall trees or in cliffs, occasionally on electrical towers; feeds mostly on fish and waterfowl	**Seismic Retrofit Area: Present.** One to two pairs have nested along the northwest arm of Anderson Reservoir since a single pair was first detected in 2010. Two pairs nested successfully in 2020, with nests approximately 0.8 and 1.8 miles northwest of the spillway; in 2021 and 2022, two pairs were present but only one nested successfully (Valley Water 2020e ~~2020a~~, 2021c ~~2021e~~, 2022a ~~2022b~~). Additional nonbreeding birds are present as well, primarily in winter. Bald eagles forage throughout the reservoir and adjacent grasslands, as well as nearby at the Kirby Canyon Landfill. **Conservation Measures Project Area: Present.** A pair of bald eagles nested, apparently unsuccessfully, near Pond 3 at the Ogier Ponds in 2019 (Valley Water 2022a ~~2022b~~). Although the species has not been known or suspected of nesting there since then, bald eagles occasionally forage at the Ogier Ponds, especially in winter. The species also occasionally forages in the Coyote Percolation Pond near the Coyote Percolation Dam CM. It is not expected to forage in the closed-canopy riparian habitat at the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach areas. **Expanded Study Area: Present.** Bald eagles have not nested in or near any parts of the study area outside the Project Area, though the species is occasionally recorded foraging in North Coyote Valley (apparently on waterfowl and California ground squirrels) (Cornell Lab of Ornithology 2022).
Swainson's hawk *Buteo swainsoni*	ST	Nests in trees surrounded by foraging habitat, which consists of extensive marsh, pasture, grassland, or agricultural land	**Seismic Retrofit Area: Absent as Breeder.** Swainson's hawk is currently known to occur in Santa Clara County primarily as a scarce transient during migration. It apparently nested in small numbers in the county historically, and there is an 1894 nest record from the Berryessa area (currently in eastern San José) (Bousman 2007b). Each year from 2013 to 2020, a pa~~ir of Sw~~ainson~~'s haw~~ks nest~~ed near~~ Coyote Creek in northern Coyote Valley, approximately 6 miles northwest of the Seismic Retrofit Area, providing the first county nesting record since the 1890s (Phillips et al. 2014). The only other modern record of nesting Swainson's hawk in Santa Clara County has been along State Route 152 southeast of Gilroy, from 2020 through 2022 (Klein et al. 2022). Although nesting Swainson's hawks may be returning to the region, there is no expectation that the species would nest within or adjacent to the Seismic Retrofit Area. **Conservation Measures Project Area: Absent as Breeder.** The pair that nested in Coyote Valley from 2013 to 2020 did so approximately 2 miles northwest of the Ogier Ponds and 2.8 miles southeast of the Coyote Percolation Dam. This s~~pecies cou~~ld occasionally forage in or near either area, but it does not nest within or adjacent to the Conservation Measures Project Area. It is not expected to forage in the closed-canopy riparian habitat at the North Channel Reach Extension and Live Oak Restoration Reach areas. **Expanded Study Area: Absent as Breeder.** Swainson's hawks could occur as infrequent migrants, but they do not breed in or near any parts of the study area outside the Project Area.
